Introduction

- ▶ Stephan Schulz
 - ▶ Dipl.-Inform., U. Kaiserslautern, 1995
 - ▶ Dr. rer. nat., TU München, 2000
 - ▶ Visiting professor, U. Miami, 2002
 - ▶ Visiting professor, U. West Indies, 2005
 - ▶ Lecturer (Hildesheim, Offenburg, ...) since 2009
 - ▶ Industry experience: Building Air Traffic Control systems
 - ▶ System engineer, 2005
 - ▶ Project manager, 2007
 - ▶ Product Manager, 2013
 - ▶ Professor, DHBW Stuttgart, 2014

Research: Logic & Automated Reasoning

Introduction

► Jan Hladik

- ▶ Dipl.-Inform.: RWTH Aachen, 2001
- ▶ Dr. rer. nat.: TU Dresden, 2007
- ▶ Industry experience: SAP Research
 - ▶ Work in publicly funded research projects
 - ▶ Collaboration with SAP product groups
 - ▶ Supervision of Bachelor, Master, and PhD students
- ▶ Professor: DHBW Stuttgart, 2014

**Research: Semantic Web, Semantic Technologies,
Automated Reasoning**

Literature

► Scripts

- The most up-to-date version of this document as well as auxiliary material will be made available online at

`http://wwwlehre.dhbw-stuttgart.de/~sschulz/fla2017.html`

and

`http://wwwlehre.dhbw-stuttgart.de/~hladik/FLA`

► Books

- John E. Hopcroft, Rajeev Motwani, Jeffrey D. Ullman: [Introduction to Automata Theory, Languages, and Computation](#)

Computing Environment

- ▶ For practical exercises, you will need a complete Linux/UNIX environment. If you do not run one natively, there are several options:
 - ▶ You can install VirtualBox (<https://www.virtualbox.org>) and then install e.g. Ubuntu (<http://www.ubuntu.com/>) on a virtual machine
 - ▶ For Windows, you can install the **complete** UNIX emulation package Cygwin from <http://cygwin.com>
 - ▶ For MacOS, you can install fink (<http://fink.sourceforge.net/>) or MacPorts (<https://www.macports.org/>) and the necessary tools
- ▶ You will need at least flex, bison, gcc, make, and a good text editor

Lecture-specific material

Bonus Exercises

Selected Solutions

Formal language concepts

Alphabet: finite set Σ of symbols (characters)

- ▶ $\{a, b, c\}$

Word: finite sequence w of characters (string)

- ▶ $ab \neq ba$

Language: (possibly infinite) set L of words

- ▶ $\{ab, ba\} = \{ba, ab\}$

Formal: L defined precisely

- ▶ opposed to natural languages, where there are borderline cases

Some formal languages

Example

- ▶ names in a phone directory
- ▶ phone numbers in a phone directory
- ▶ legal C identifiers
- ▶ legal C programs
- ▶ legal [HTML 4.01 Transitional](#) documents
- ▶ empty set
- ▶ ASCII strings
- ▶ Unicode strings

More?

Language classes

This course: four classes of different complexity and expressivity

- 1 **regular** languages: limited power, but easy to handle
 - ▶ “strings that start with a letter, followed by up to 7 letters or digits”
 - ▶ legal C identifiers
 - ▶ phone numbers
- 2 **context-free** languages: more expressive, but still feasible
 - ▶ “every <token> is matched by </token>”
 - ▶ **nested** dependencies
 - ▶ (most aspects of) legal C programs
 - ▶ many natural languages (English, German)

Jan says that we
let
the children
help
Hans
paint
the house

Jan sagt, dass wir
die Kinder
dem Hans
das Haus
anstreichen
helfen
ließen

Language classes (cont')

- 3 context-sensitive languages: even more expressive, difficult to handle computationally

- ▶ “every variable has to be declared before it is used”
(arbitrary sequence, arbitrary amounts of code in between)
- ▶ cross-serial dependencies
- ▶ (remaining aspects of) legal C programs
- ▶ most remaining natural languages (Swiss German)

Jan säit das mer
d' chind
em Hans
es huus
lönd
helfe
aastriche

Jan says that we
the children
Hans
the house
let
help
paint

- 4 recursively enumerable languages: most general (Chomsky) class; undecidable

- ▶ all (valid) mathematical theorems (in first-order logic)
- ▶ programs terminating on a particular input

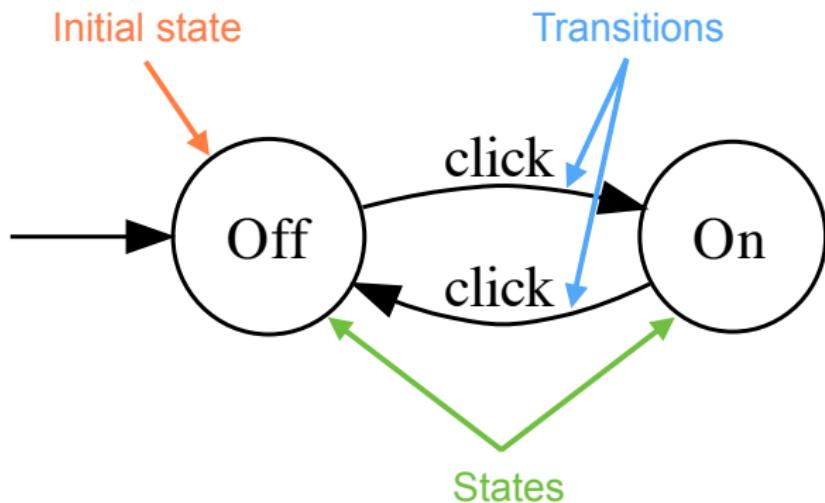

Automata

- ▶ abstract formal machine model, characterised by **states, letters, transitions, and external memory**
- ▶ accept words

For every language class discussed in this course, a machine model exists such that for every **language L** there is an **automaton $\mathcal{A}(L)$** that accepts exactly the words in L .

regular	~> finite automaton/finite state machine
context-free	~> pushdown automaton
context-sensitive	~> linearly bounded Turing machine
recursively enumerable	~> (unbounded) Turing machine

Example: Finite Automaton

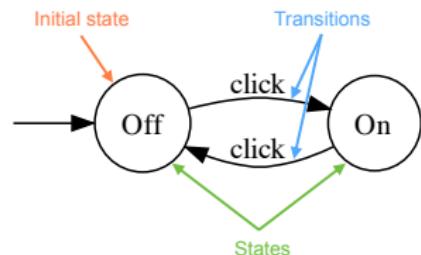

Example: Finite Automaton

Formally:

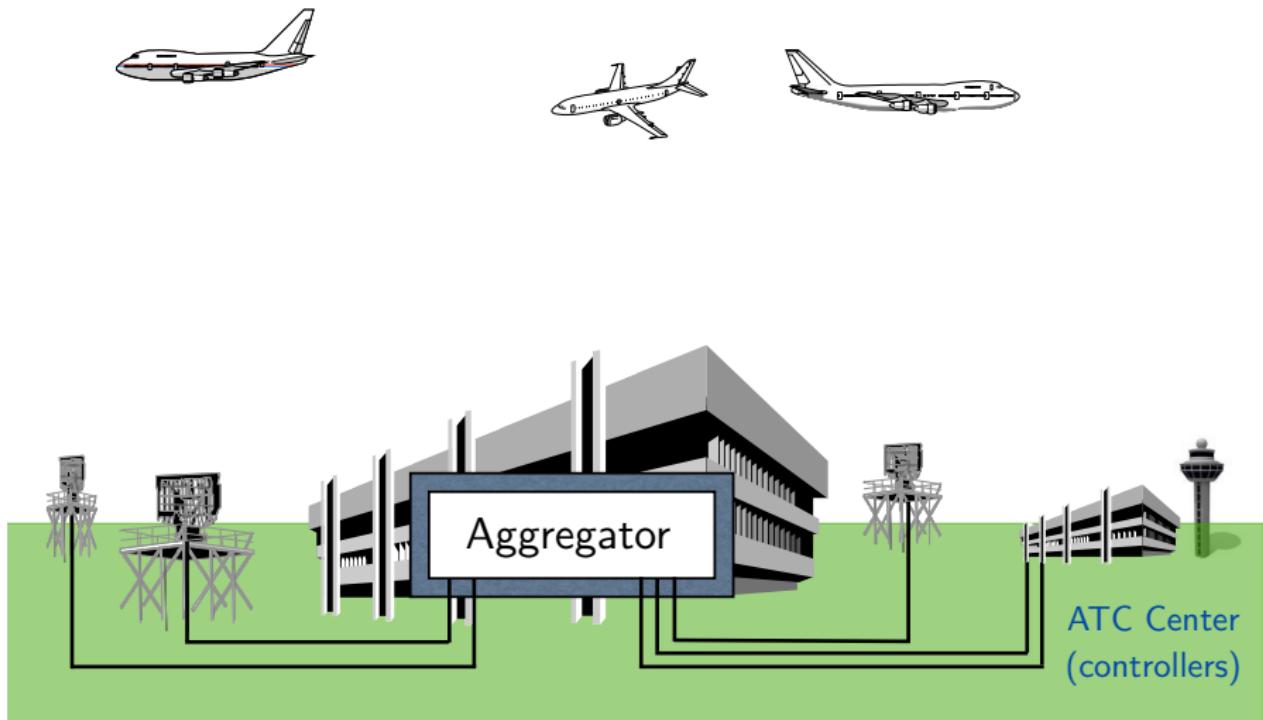

- ▶ $Q = \{\text{Off}, \text{On}\}$ is the set of states
- ▶ $\Sigma = \{\text{click}\}$ is the alphabet
- ▶ The transition function δ is given by

δ	click
Off	On
On	Off

- ▶ The initial state is Off
- ▶ There are no accepting states

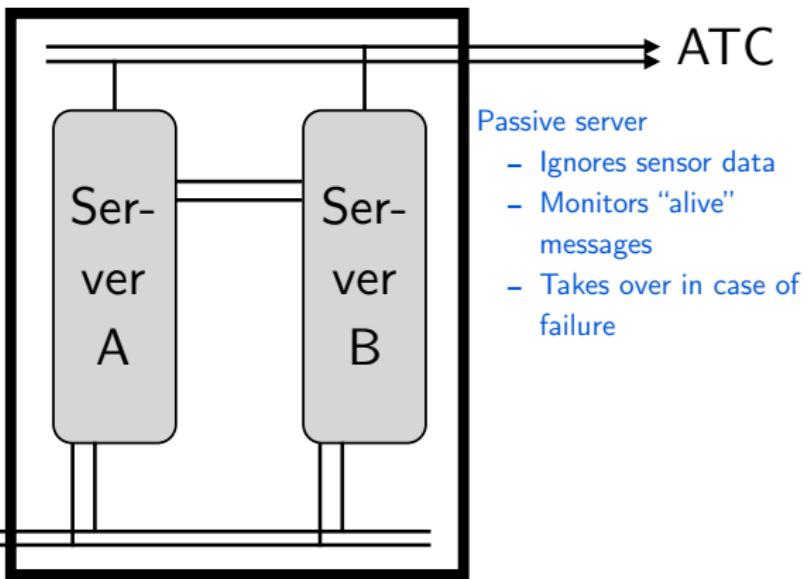

ATC scenario

ATC redundancy

Aktive server:

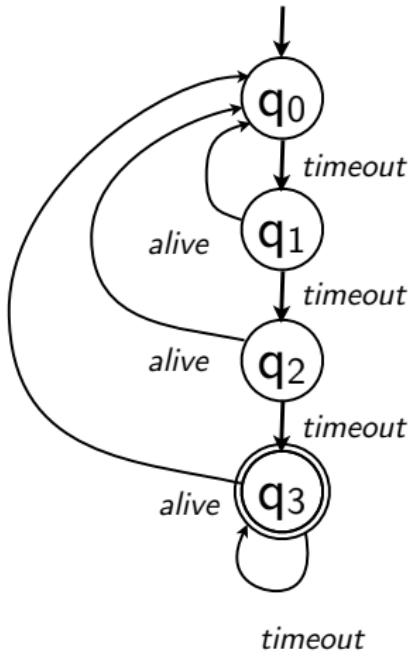

- Accepts sensor data
- Provides ASP
- Sends “alive” messages

Passive server

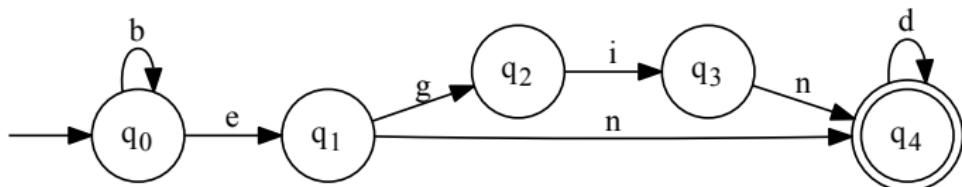

- Ignores sensor data
- Monitors “alive” messages
- Takes over in case of failure

Finite automaton to the rescue

- ▶ Two events (“letters”)
 - ▶ **timeout**: 0.1 seconds have passed
 - ▶ **alive**: message from active server
- ▶ States q_0, q_1, q_2 : Server is passive
 - ▶ No processing of input
 - ▶ No sending of alive messages
- ▶ State q_3 : Server becomes active
 - ▶ Process input, provide output to ATC
 - ▶ Send alive messages every 0.1 seconds

Exercise: Finite automaton

Does this automaton accept the words *begin, end, bind, bend*?

Turing Machine

“Universal computer”

- ▶ Very simple model of a computer
 - ▶ Infinite tape, one read/write head
 - ▶ Tape can store letters from a alphabet
 - ▶ Finite automaton controls read/write and movement operations
- ▶ Very powerful model of a computer
 - ▶ Can compute anything any real computer can compute
 - ▶ Can compute anything an “ideal” real computer can compute
 - ▶ Can compute everything a human can compute (?)

Formal grammars

Formalism to **generate** (rather than accept) words over alphabet

terminal symbols: may appear in the produced word (alphabet)

non-terminal symbols: may not appear in the produced word
(temporary symbols)

production rules: $l \rightarrow r$ means: l can be replaced by r anywhere
in the word

Example

Grammar for arithmetic expressions over $\{0, 1\}$

$$\Sigma = \{0, 1, +, \cdot, (,)\}$$

$$N = \{E\}$$

$$\begin{aligned} P = & \{E \rightarrow 0, E \rightarrow 1, \\ & E \rightarrow (E) \\ & E \rightarrow E + E \\ & E \rightarrow E \cdot E\} \end{aligned}$$

Exercise: Grammars

Using

- ▶ the non-terminal symbol S
- ▶ the terminal symbols b, d, e, g, i, n
- ▶ the production rules

$S \rightarrow begin, beg \rightarrow e, in \rightarrow ind, in \rightarrow n, eg \rightarrow egg, ggg \rightarrow b$

can you generate the words *bend* and *end* starting from the symbol S ?

- ▶ If yes, how many steps do you need?
- ▶ If no, why not?

Questions about formal languages

- ▶ For a given language L , how can we find
 - ▶ a corresponding automaton \mathcal{A}_L ?
 - ▶ a corresponding grammar G_L ?
- ▶ What is the simplest automaton for L ?
 - ▶ “simplest” meaning: weakest possible language class
 - ▶ “simplest” meaning: least number of elements
- ▶ How can we use formal descriptions of languages for compilers?
 - ▶ detecting legal words/reserved words
 - ▶ testing if the structure is legal
 - ▶ understanding the meaning by analysing the structure

More questions about formal languages

Closure properties: if L_1 and L_2 are in a class, does this also hold for

- ▶ the **union** of L_1 and L_2 ,
- ▶ the **intersection** of L_1 and L_2 ,
- ▶ the **concatenation** of L_1 and L_2 ,
- ▶ the **complement** of L_1 ?

Decision problems: for a word w and languages L_1 and L_2 (given by grammars or automata),

- ▶ does $w \in L_1$ hold?
- ▶ is L_1 finite?
- ▶ is L_1 empty?
- ▶ does $L_1 = L_2$ hold?

Abandon all hope...

Example applications for formal languages and automata

- ▶ HTML and web browsers
- ▶ Speech recognition and understanding grammars
- ▶ Dialog systems and AI (Siri, Watson)
- ▶ Regular expression matching
- ▶ Compilers and interpreters of programming languages

Alphabets

Definition (Alphabet)

An **alphabet** Σ is a finite, non-empty set of characters (symbols, letters).

$$\Sigma = \{c_1, \dots, c_n\}$$

Example

- 1 $\Sigma_{\text{bin}} = \{0, 1\}$ can express integers in the binary system.
- 2 The English language is based on $\Sigma_{\text{en}} = \{a, \dots, z, A, \dots, Z\}$.
- 3 $\Sigma_{\text{ASCII}} = \{0, \dots, 127\}$ represents the set of ASCII characters [American Standard Code for Information Interchange] coding letters, digits, and special and control characters.

Alphabets: ASCII code chart

ASCII Code Chart

	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F
0	NUL	SOH	STX	ETX	EOT	ENQ	ACK	BEL	BS	HT	LF	VT	FF	CR	SO	SI

6	'	a	b	c	d	e	f	g	h	i	j	k	l	m	n	o
7	p	q	r	s	t	u	v	w	x	y	z	{		}	~	DEL

Words

Definition (Word)

- ▶ A **word** over the alphabet Σ is a finite sequence (list) of characters of Σ :

$$w = c_1 \dots c_n \quad \text{with} \quad c_1, \dots, c_n \in \Sigma.$$

- ▶ The **empty word** with no characters is written as ε .
- ▶ The set of all words over an alphabet Σ is represented by Σ^* .

In programming languages, words are often referred to as **strings**.

Words

Example

- 1 Using Σ_{bin} , we can define the words $w_1, w_2 \in \Sigma_{\text{bin}}^*$:

$$w_1 = 01100 \quad \text{and} \quad w_2 = 11001$$

- 2 Using Σ_{en} , we can define the word $w \in \Sigma_{\text{en}}^*$:

$$w = \text{example}$$

Properties of words

Definition (Length, character access)

- ▶ The **length** $|w|$ of a word w is the number of characters in w .
- ▶ The **number of occurrences** of a character c in w is denoted as $|w|_c$.
- ▶ The **individual characters** within words are accessed using the terminology $w[i]$ with $i \in \{1, 2, \dots, |w|\}$.

Example

- ▶ $|\text{example}| = 7$ and $|\varepsilon| = 0$
- ▶ $|\text{example}|_e = 2$ and $|\text{example}|_k = 0$
- ▶ $\text{example}[4] = m$

Appending words

Definition (Concatenation of words)

For words w_1 and w_2 , the concatenation $w_1 \cdot w_2$ is defined as w_1 followed by w_2 .

$w_1 \cdot w_2$ is often simply written as w_1w_2 .

Example

Let $w_1 = 01$ and $w_2 = 10$.

Then the following holds:

$$w_1w_2 = 0110 \quad \text{and} \quad w_2w_1 = 1001$$

Iterated concatenation

We denote the set of natural numbers $\{0, 1, \dots\}$ by \mathbb{N} .

Definition (Power of a word)

For $n \in \mathbb{N}$, the n -th power w^n of a word w concatenates the same word w n times:

$$\begin{aligned} w^0 &= \varepsilon \\ w^n &= w^{n-1} \cdot w \quad \text{if } n > 0 \end{aligned}$$

Example

Let $w = ab$. Then:

$$\begin{aligned} w^0 &= \varepsilon \\ w^1 &= ab \\ w^3 &= ababab \end{aligned}$$

Exercise: Operations on words

Given the alphabet $\Sigma = \{a, b, c\}$ and the words

- ▶ $u = abc$
- ▶ $v = aa$
- ▶ $w = cb$

what is denoted by the following expressions?

- 1 $u^2 \cdot w$
- 2 $v \cdot \varepsilon \cdot w \cdot u^0$
- 3 $|u^3|_a$
- 4 $v \cdot a^2 \cdot (v[4])$
- 5 $(v \cdot a^2 \cdot v)[4]$
- 6 $|w^0|$
- 7 $|w^0 \cdot w|$

Formal languages

Definition (Formal language)

For an alphabet Σ , a **formal language over Σ** is a subset $L \subseteq \Sigma^*$.

Example

Let $L_{\mathbb{N}} = \{1w \mid w \in \Sigma_{\text{bin}}^*\} \cup \{0\}$.

Then $L_{\mathbb{N}}$ is the set of all words that represent integers using the binary system (all words starting with 1 and the word 0):

$$100 \in L_{\mathbb{N}} \quad \text{but} \quad 010 \notin L_{\mathbb{N}}.$$

Numeric value of a binary word

Definition (Numeric value)

We define the function

$$n : L_{\mathbb{N}} \rightarrow \mathbb{N}$$

as the function returning the numeric value of a word in the language $L_{\mathbb{N}}$. This means

- (a) $n(0) = 0,$
- (b) $n(1) = 1,$
- (c) $n(w0) = 2 \cdot n(w) \text{ for } |w| > 0,$
- (d) $n(w1) = 2 \cdot n(w) + 1 \text{ for } |w| > 0.$

Prime numbers as a language

Definition (Prime numbers)

We define the language $L_{\mathbb{P}}$ as the language representing prime numbers in the binary system:

$$L_{\mathbb{P}} = \{w \in L_{\mathbb{N}} \mid n(w) \in \mathbb{P}\}.$$

One way to formally express the set of all prime numbers is

$$\mathbb{P} = \{p \in \mathbb{N} \mid p \neq 1 \wedge \{t \in \mathbb{N} \mid \exists k \in \mathbb{N} : k \cdot t = p\} = \{1, p\}\}.$$

C functions as a language

Definition

We define the language $L_C \subset \Sigma_{\text{ASCII}}^*$ as the set of all C function definitions with a declaration of the form:

```
char* f(char* x);
```

(where f and x are legal C identifiers).

Then L_C contains the ASCII code of all those definitions of C functions processing and returning a string.

Examples

- ▶ `char* f(char* x){return x;}` $\in L_C$
- ▶ `char* f(char* x){return "";` $\in L_C$
- ▶ `char* f(char* x, int y){return "";` $\notin L_C$
- ▶ Harakiri $\notin L_C$

C function evaluations as a language

Definition

Using the alphabet $\Sigma_{\text{ASCII}^+} = \Sigma_{\text{ASCII}} \cup \{\dagger\}$, we define the [universal language](#)

$$L_u = \{f\dagger x\dagger y \mid (\text{a}) \text{ and } (\text{b}) \text{ and } (\text{c})\} \quad \text{with}$$

- (a) $f \in L_C$ (i.e. f is a C function mapping strings to strings),
- (b) $x, y \in \Sigma_{\text{ASCII}}^*$,
- (c) applying f to x terminates and returns y .

Examples

- ▶ `char* f(char* x){return x; }†aaa†aaa` $\in L_u$
- ▶ `char* f(char* x){return x; }†aaa†bbb` $\notin L_u$
- ▶ `char* f(char* x){return ""; }†aaa†` $\in L_u$

Formal languages can be highly complex

Formal languages have a wide scope:

- ▶ Testing whether a word belongs to $L_{\mathbb{N}}$ is straightforward
- ▶ The same test for $L_{\mathbb{P}}$ is more complex
- ▶ The test for L_C requires a proper C parser
- ▶ Later we will see that there is no algorithm that will correctly perform the membership test for L_u

```
def inN(x):  
    if x=="0":  
        return True  
    if x=="":  
        return False  
    if x[0]!="1":  
        return False  
    for c in x[1:]:  
        if c!="0" and c!="1":  
            return False  
    return True
```

Abandon all hope...

Product

Definition (Product of formal languages)

Given an alphabet Σ and the formal languages $L_1, L_2 \subseteq \Sigma^*$, we define the product

$$L_1 \cdot L_2 = \{w_1 \cdot w_2 \mid w_1 \in L_1, w_2 \in L_2\}.$$

Example

Using the alphabet Σ_{en} , we define the languages

$$L_1 = \{ab, bc\} \quad \text{and} \quad L_2 = \{ac, cb\}.$$

The product is

$$L_1 \cdot L_2 = \{abac, abcb, bcac, bccb\}.$$

Power

Definition (Power of a language)

Given an alphabet Σ , a formal language $L \subseteq \Sigma^*$, and an integer $n \in \mathbb{N}$, we define the ***n*-th power** of L (recursively) as follows:

$$\begin{aligned} L^0 &= \{\varepsilon\} \\ L^n &= L^{n-1} \cdot L \end{aligned}$$

Example

Using the alphabet Σ_{en} , we define the language $L = \{ab, ba\}$. Thus:

$$L^0 = \{\varepsilon\}$$

$$L^1 = \{\varepsilon\} \cdot \{ab, ba\} = \{ab, ba\}$$

$$L^2 = \{ab, ba\} \cdot \{ab, ba\} = \{abab, abba, baab, baba\}$$

The Kleene Star operator

Definition (Kleene Star)

Given an alphabet Σ and a formal language $L \subseteq \Sigma^*$, we define the **Kleene star** operator as

$$L^* = \bigcup_{n \in \mathbb{N}} L^n.$$

Example

Using the alphabet Σ_{en} , we define the language $L = \{a\}$. Thus:

$$L^* = \{a^n \mid n \in \mathbb{N}\}.$$

Exercise: formal languages

Given the alphabet Σ_{bin} and the language $L = \{1\}$, formally describe the following:

- a) the language $M = L^* \setminus \{\varepsilon\}$
- b) the set $N = \{n(w) \mid w \in M\}$
- c) the language $M^- = \{w \mid n(w) - 1 \in N\}$
- d) the language $M^+ = \{w \mid n(w) + 1 \in N\}$

Regular expressions

Compact and convenient way to represent a set of strings

- ▶ Characterize tokens for compilers
- ▶ Describe search terms for a database
- ▶ Filter through genomic data
- ▶ Extract URLs from web pages
- ▶ Extract email addresses from web pages

**The set of all regular expressions (over an alphabet)
is a formal language**

Each single regular expression describes a formal language

Introductory Examples

Consider $\Sigma_{\text{bin}} = \{0, 1\}$. With regular expressions we can conveniently and rigorously describe many languages:

- ▶ $1(0 + 1)^*$ – all words beginning with a 1 (also known as $L_{\mathbb{N}} \setminus \{0\}$)
- ▶ 11^* – all words consisting of one ore more letters 1 (M from the last exercise)
- ▶ $0(10)^* + (10)^* + 1(01)^* + (01)^*$ – the language of all words where no two subsequent characters are the same

Reminder: Power sets

Definition (Power set of a set)

- ▶ Assume a set S . Then the power set of S , written as 2^S , is the set of all subsets of S .
- ▶ In particular, if Σ is an alphabet, 2^{Σ^*} is the set of all subsets of Σ^* and hence the set of all possible formal languages over Σ .

Example

$$\begin{aligned}2^{\Sigma_{\text{bin}}} &= 2^{\{0,1\}} = \{\{\}, \{0\}, \{1\}, \{0,1\}\}, \\2^{\Sigma_{\text{bin}}^*} &= 2^{\{\varepsilon, 0, 1, 00, 01, \dots\}} \\&= \{\{\}, \{\varepsilon\}, \{0\}, \{1\}, \{00\}, \{01\}, \dots \\&\quad \dots \{\varepsilon, 0\}, \{\varepsilon, 1\}, \{\varepsilon, 00\}, \{\varepsilon, 01\}, \dots \\&\quad \dots \{010, 1110, 10101\}, \dots\}.\end{aligned}$$

Regular expressions and formal languages

A regular expression over Σ ...

- ▶ ... is a word over the extended alphabet $\Sigma \cup \{\emptyset, \varepsilon, +, \cdot, ^*, (,)\}$
 - ▶ Note that we implicitly assume that $\{\emptyset, \varepsilon, +, \cdot, ^*, (,)\} \cap \Sigma = \{\}$
 - ▶ \emptyset denotes a regular expression (syntax)
 - ▶ $\{\}$ denotes the empty set (semantics)
- ▶ ... describes a formal language over Σ

Terminology

The following terms are defined on the next slides:

- ▶ R_Σ is the set of all regular expressions over the alphabet Σ .
- ▶ The function $L : R_\Sigma \rightarrow 2^{\Sigma^*}$ assigns a formal language $L(r) \subseteq \Sigma^*$ to each regular expression r .

Regular expressions and their languages (1)

Definition (Regular expressions)

The set of regular expressions R_Σ over the alphabet Σ is defined as follows:

- 1 The regular expression \emptyset denotes the empty language.
 $\emptyset \in R_\Sigma$ and $L(\emptyset) = \{\}$
- 2 The regular expression ε denotes the language containing only the empty word.
 $\varepsilon \in R_\Sigma$ and $L(\varepsilon) = \{\varepsilon\}$
- 3 Each symbol in the alphabet Σ is a regular expression.
 $c \in \Sigma \Rightarrow c \in R_\Sigma$ and $L(c) = \{c\}$

Regular expressions and their languages (2)

Definition (Regular expressions (cont'))

- 4 The operator $+$ denotes the **union** of the languages of r_1 and r_2 .
 $r_1 \in R_\Sigma, r_2 \in R_\Sigma \Rightarrow r_1 + r_2 \in R_\Sigma$ and $L(r_1 + r_2) = L(r_1) \cup L(r_2)$
- 5 The operator \cdot denotes the **product** of the languages of r_1 and r_2 .
 $r_1 \in R_\Sigma, r_2 \in R_\Sigma \Rightarrow r_1 \cdot r_2 \in R_\Sigma$ and $L(r_1 \cdot r_2) = L(r_1) \cdot L(r_2)$
- 6 The **Kleene star** of a regular expression r denotes the Kleene star of the language of r .
 $r \in R_\Sigma \Rightarrow r^* \in R_\Sigma$ and $L(r^*) = (L(r))^*$
- 7 **Brackets** can be used to group regular expressions without changing their language.
 $r \in R_\Sigma \Rightarrow (r) \in R_\Sigma$ and $L((r)) = L(r)$

Equivalence of regular expressions

Definition (Equivalence and precedence)

- ▶ Two regular expressions r_1 and r_2 are **equivalent** if they denote the same language: $r_1 \doteq r_2$ if and only if $L(r_1) = L(r_2)$
- ▶ The operators have the following **precedence**:
 $(\dots) > * > \cdot > +$
- ▶ The product operator \cdot can be omitted.

Example

$$a + b \cdot c^* \doteq a + (b \cdot (c^*))$$

$$ac + bc^* \doteq a \cdot c + b \cdot c^*$$

Note: Some authors (and tools) use $|$ as the union operator.

Examples for regular expressions

Example

Let $\Sigma_{abc} = \{a, b, c\}$.

- ▶ The regular expression $r_1 = (a + b + c)(a + b + c)$ describes all the words of exactly two symbols:

$$L(r_1) = \{w \in \Sigma_{abc}^* \mid |w| = 2\}$$

- ▶ The regular expression $r_2 = (a + b + c)(a + b + c)^*$ describes all the words of one or more symbols:

$$L(r_2) = \{w \in \Sigma_{abc}^* \mid |w| \geq 1\}$$

Exercise: regular expressions

- 1 Using the alphabet $\Sigma_{abc} = \{a, b, c\}$, give a regular expression r_1 for all the words $w \in \Sigma_{abc}^*$ containing exactly one a or exactly one b .
- 2 Formally describe $L(r_1)$ as a set.
- 3 Using the alphabet $\Sigma_{abc} = \{a, b, c\}$, give a regular expression r_2 for all the words containing at least one a and at least one b .
- 4 Using the alphabet $\Sigma_{bin} = \{0, 1\}$, give a regular expression for all the words whose third last symbol is 1 .
- 5 Using the alphabet Σ_{bin} , give a regular expression for all the words not containing the string 110 .
- 6 Which language is described by the regular expression

$$r_6 = (1 + \varepsilon)(00^*1)^*0^*?$$

End lecture 2

Algebraic operations on regular expressions

Theorem

- 1 $r_1 + r_2 \doteq r_2 + r_1$ (*commutative law*)
- 2 $(r_1 + r_2) + r_3 \doteq r_1 + (r_2 + r_3)$ (*associative law*)
- 3 $(r_1 r_2) r_3 \doteq r_1 (r_2 r_3)$ (*associative law*)
- 4 $\emptyset r \doteq \emptyset$
- 5 $\varepsilon r \doteq r$
- 6 $\emptyset + r \doteq r$
- 7 $(r_1 + r_2) r_3 \doteq r_1 r_3 + r_2 r_3$ (*distributive law*)
- 8 $r_1(r_2 + r_3) \doteq r_1 r_2 + r_1 r_3$ (*distributive law*)

Proof of some rules

Proof of Rule 1 ($r_1 + r_2 \doteq r_2 + r_1$).

$$L(r_1 + r_2) = L(r_1) \cup L(r_2) = L(r_2) \cup L(r_1) = L(r_2 + r_1)$$

Proof of Rule 4 ($\emptyset r \doteq \emptyset$).

$$\begin{aligned} L(\emptyset r) &\stackrel{\text{Def. concat}}{=} L(\emptyset) \cdot L(r) \\ &\stackrel{\text{Def. empty regexp}}{=} \{\} \cdot L(r) \\ &\stackrel{\text{Def. product}}{=} \{w_1 w_2 \mid w_1 \in \{\}, w_2 \in L(r)\} \\ &= \{\} \\ &\stackrel{\text{Def. empty regexp}}{=} L(\emptyset) \end{aligned}$$

Algebraic operations on regular expressions (cont.)

Theorem

$$9 \quad r + r \doteq r$$

$$10 \quad (r^*)^* \doteq r^*$$

$$11 \quad \emptyset^* \doteq \varepsilon$$

$$12 \quad \varepsilon^* \doteq \varepsilon$$

$$13 \quad r^* \doteq \varepsilon + r^*r$$

$$14 \quad r^* \doteq (\varepsilon + r)^*$$

15 $\varepsilon \notin L(s)$ and $r \doteq rs + t \longrightarrow r \doteq ts^*$ (proof by Arto Salomaa)

16 $r^*r \doteq rr^*$ (see Lemma: Kleene Star below)

17 $\varepsilon \notin L(s)$ and $r \doteq sr + t \longrightarrow r \doteq s^*t$ (Arden's Lemma)

Lemma: Kleene Star (1)

Lemma (Kleene Star)

$$u^*u \doteq uu^*$$

Proof of Case 1: $\varepsilon \notin L(u)$.

$$\begin{aligned} u^*u &\doteq (\varepsilon + u^*u)u && (\text{by 13. } (r)^* \doteq \varepsilon + (r)^*r) \\ &\doteq (u^*u + \varepsilon)u && (\text{by 1. } r_1 + r_2 \doteq r_2 + r_1) \\ &\doteq u^*uu + u && (\text{by 7. } (r_1 + r_2)r_3 \doteq r_1r_3 + r_2r_3) \\ &\doteq uu^* && (\text{by 15. } r \doteq rs + t \text{ with } r = u^*u, s = u, t = u) \end{aligned}$$

Lemma: Kleene Star (2)

Proof of Case 2: $\varepsilon \in L(u)$.

We show $L(u^*u) = L(u^*) = L(uu^*)$

a) Proof of $L(u^*u) \subseteq L(u^*)$

$$\begin{aligned}L(u^*u) &= L(u^*) \cdot L(u) \\&= (L(u))^* \cdot L(u) \\&= (\bigcup_{i \geq 0} L(u)^i) \cdot L(u) \\&= \bigcup_{i \geq 0} (L(u)^i \cdot L(u)) \\&= \bigcup_{i \geq 1} L(u)^i \\&\subseteq L(u^*)\end{aligned}$$

b) Proof of $L(u^*u) \supseteq L(u^*)$

$$\begin{aligned}L(u^*u) &= \{tv \mid t \in L(u^*), v \in L(u)\} \\&\supseteq \{tv \mid t \in L(u^*), v = \varepsilon\} \\&= \{t \mid t \in L(u^*)\} \\&= L(u^*)\end{aligned}$$

- ▶ a) and b) imply $L(u^*u) = L(u^*)$
- ▶ $L(uu^*) = L(u^*)$: strictly analogous

A note on Arto/Arden

- ▶ Arto: $\varepsilon \notin L(s)$ and $r \doteq rs + t \longrightarrow r \doteq ts^*$
- ▶ Why do we need $\varepsilon \notin L(s)$?
 - ▶ This guarantees that **only** words of the form ts^* are in $L(r)$
 - ▶ Example: $r \doteq rs + t$ mit $s = b^*$, $t = a$.
 - ▶ If we could apply Arto, the result would be $r \doteq a(b^*)^* \doteq ab^*$
 - ▶ But $L = \{ab^*\} \cup \{b^*\}$ also fulfills the equation, i.e. there is no single unique solution in this case
 - ▶ Intuitively: $\varepsilon \in L(s)$ is a second escape from the recursion that bypasses t
- ▶ The case for Arden's lemma ($\varepsilon \notin L(s)$ and $r \doteq sr + t \longrightarrow r \doteq s^*t$) is analogous

Exercise: Algebra on regular expressions

- 1 Prove the equivalence using only algebraic operations:

$$r^* \doteq \varepsilon + r^*.$$

- 2 Simplify the regular expression s using only algebraic operations:

$$s = 0(\varepsilon + 0 + 1)^* + (\varepsilon + 1)(1 + 0)^* + \varepsilon.$$

- 3 Prove the equivalence using only algebraic equivalences:

$$10(10)^* \doteq 1(01)^*0.$$

Selected Solutions

Finite Automata: Motivation

- ▶ Simple model of computation
- ▶ Can recognize **regular languages**
- ▶ Equivalent to regular expressions
 - ▶ We can automatically generate a FA from a RE
 - ▶ We can automatically generate an RE from an FA
- ▶ Two variants:
 - ▶ Deterministic (DFA, now)
 - ▶ Non-deterministic (NFA, later)
- ▶ Easy to implement in actual programs

Deterministic Finite Automata: Idea

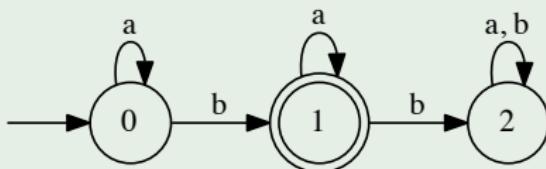

Deterministic finite automaton (DFA)

- ▶ is in one of finitely many **states**
- ▶ starts in the **initial state**
- ▶ processes **input** from left to right
 - ▶ changes state depending on character read
 - ▶ determined by **transition function**
 - ▶ no rewinding!
 - ▶ no writing!
- ▶ accepts input if
 - ▶ after reading the entire input
 - ▶ a **final state** is reached

DFA \mathcal{A} for a^*ba^*

Example (Automaton \mathcal{A})

\mathcal{A} is a simple DFA recognizing the regular language a^*ba^* .

- ▶ \mathcal{A} has three **states**, 0, 1 and 2.
- ▶ It operates on the **alphabet** $\{a, b\}$.
- ▶ The **transition function** is indicated by the arrows.
- ▶ 0 is the **initial** state (with an arrow “pointing at it from anywhere”).
- ▶ 1 is an **accepting** state (represented as a double circle).
- ▶ 2 is also called a **junk** state (once it is reached, the word can never be accepted).

DFA: formal definition

Definition (Deterministic Finite Automaton)

A **deterministic finite automaton** (DFA) is a quintuple $\mathcal{A} = (Q, \Sigma, \delta, q_0, F)$ with the following components

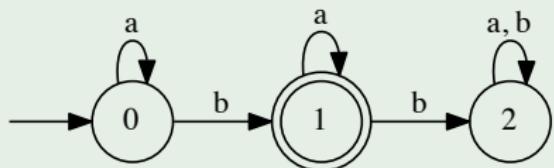

- ▶ Q is a finite set of **states**.
- ▶ Σ is the (finite) input **alphabet**.
- ▶ $\delta : Q \times \Sigma \rightarrow Q$ is the **transition function**.
- ▶ $q_0 \in Q$ is the **initial state**.
- ▶ $F \subseteq Q$ is the set of final (or **accepting**) states.

Notes:

- ▶ δ is a **total** function – there has to be a transition from every state for every letter
- ▶ ... but automata with **partial** transition functions can be “repaired” into a proper DFA by adding a junk state

Formal definition of \mathcal{A}

Example

\mathcal{A} is expressed as $(Q, \Sigma, \delta, q_0, F)$ with

- ▶ $Q = \{0, 1, 2\}$
- ▶ $\Sigma = \{a, b\}$
- ▶ $\delta(0, a) = 0; \delta(0, b) = 1, \delta(1, a) = 1; \delta(1, b) = \delta(2, a) = \delta(2, b) = 2$
- ▶ $q_0 = 0$
- ▶ $F = \{1\}$

Language accepted by an DFA

Definition (Language accepted by an automaton)

The state transition function δ is generalised to a function δ' whose second argument is a word as follows:

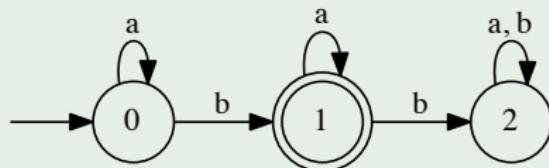

- ▶ $\delta' : Q \times \Sigma^* \rightarrow Q$
- ▶ $\delta'(q, \varepsilon) = q$ for every $q \in Q$
- ▶ $\delta'(q, wc) = \delta(\delta'(q, w), c)$ with $c \in \Sigma; w \in \Sigma^*$

The language accepted by a DFA $\mathcal{A} = (Q, \Sigma, \delta, q_0, F)$ is defined as

$$L(\mathcal{A}) = \{w \in \Sigma^* \mid \delta'(q_0, w) \in F\}.$$

Language accepted by \mathcal{A}

Example

- ▶ $\delta'(0, aa) = \delta(\delta'(0, a), a) = \delta(\delta(\delta'(0, \varepsilon), a, a) = 0$
- ▶ $\delta'(1, aaa) = 1$
- ▶ $\delta'(0, bb) = \delta'(1, b) = 2$
- ▶ $L(\mathcal{A}) = \{w \in \{a, b\}^* \mid w = a^n ba^m \text{ and } n, m \in \mathbb{N}\}$

Run of a DFA

Definition (Configuration, Run)

Let $\mathcal{A} = (Q, \Sigma, \delta, q_0, F)$ be a DFA.

A **configuration** of \mathcal{A} is a pair (q, w) with $q \in Q$ and $w \in \Sigma^*$.

A **run** of \mathcal{A} on a word $w = c_1 \cdot c_2 \cdots c_n$ is a sequence of configurations:

$$((q_0, c_1 \cdot c_2 \cdots c_n), (q_1, c_2 \cdots c_n), \dots, (q_n, \varepsilon))$$

where

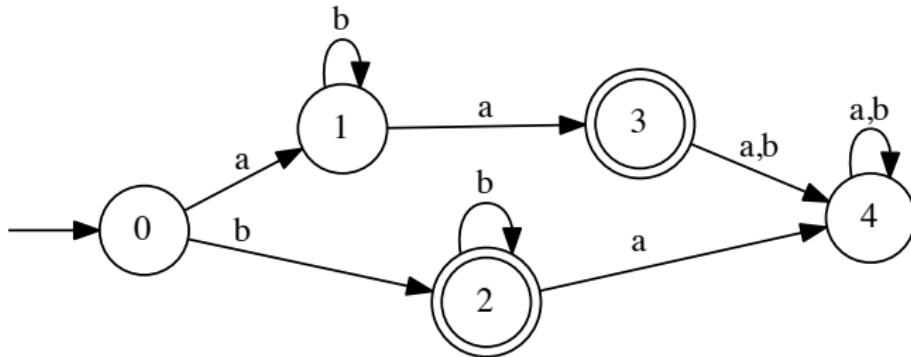

- ▶ $q_i \in Q$ holds for $1 \leq i \leq n$ and
- ▶ $\delta(q_{i-1}, c_i) = q_i$ holds for $1 \leq i \leq n$.

A run is **accepting** if $q_n \in F$ holds.

The language accepted by \mathcal{A} can alternatively be defined as the set of all words for which there exists an accepting run of \mathcal{A} .

Exercise: DFA

- 1 Given this graphical representation of a DFA \mathcal{A} :

- a) Give a regular expression describing $L(\mathcal{A})$.
- b) Give a formal definition of \mathcal{A} .

Exercise: DFA

2 Give

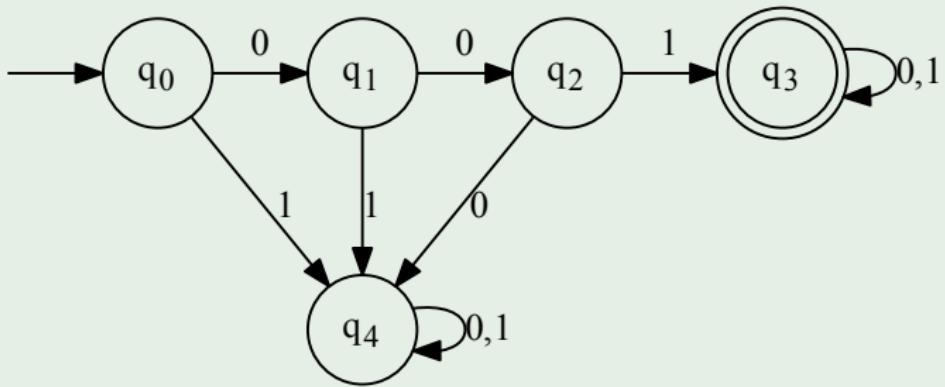

- ▶ a regular expression,
- ▶ a graphical representation, and
- ▶ a formal definition

of a DFA \mathcal{A} whose language $L(\mathcal{A}) \subset \{a, b\}^*$ contains all those words featuring the substring ab

- a) at the beginning,
- b) at arbitrary position,
- c) at the end.

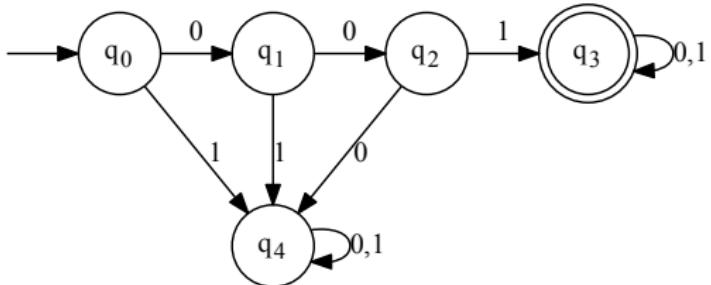

Another example

Example

Which language is recognized by the DFA?

Tabular representation of a DFA

$$\mathcal{A} = (Q, \Sigma, \delta, q_0, F)$$

- ▶ $Q = \{q_0, q_1, q_2, q_3, q_4\}$
- ▶ $\Sigma = \{0, 1\}$
- ▶ Initial state: q_0
- ▶ $F = \{q_3\}$

	δ	0	1
\rightarrow	q_0	q_0	q_1
	q_1	q_1	q_2
	q_2	q_2	q_4
*	q_3	q_3	q_3
	q_4	q_4	q_4

DFA: Tabular representation in practice

Delta	0	1	
			> easim.py fsa001.txt 10101
			Processing: 10101
->	q0	q1 q4	q0 :: 1 -> q4
	q1	q2 q4	q4 :: 0 -> q4
	q2	q4 q3	q4 :: 1 -> q4
*	q3	q3 q3	q4 :: 0 -> q4
	q4	q4 q4	q4 :: 1 -> q4
			Rejected

```
> easim.py fsa001.txt 101

q0 :: 1 -> q4
q4 :: 0 -> q4
q4 :: 1 -> q4
Rejected
```

DFAs in tabular form: exercise

- ▶ Give the following DFA ...
 - ▶ as a formal 5-tuple
 - ▶ as a diagram

parity		0	1

->	even		even odd
*	odd		odd even

- ▶ Characterize the language accepted by the DFA

DFA exercise

- ▶ Assume
 - ▶ $\Sigma = \{a, b, c\}$
 - ▶ $L_1 = \{ubw \mid u \in \Sigma^*, w \in \Sigma\}$
 - ▶ $L_2 = \{ubw \mid u \in \Sigma, w \in \Sigma^*\}$
- ▶ Group 1 (your family name starts with A-M):
Find a DFA \mathcal{A} with $L(\mathcal{A}) = L_1$
- ▶ Group 2 (your family name does not start with A-M):
Find a DFA \mathcal{A} with $L(\mathcal{A}) = L_2$

Bonus Exercises

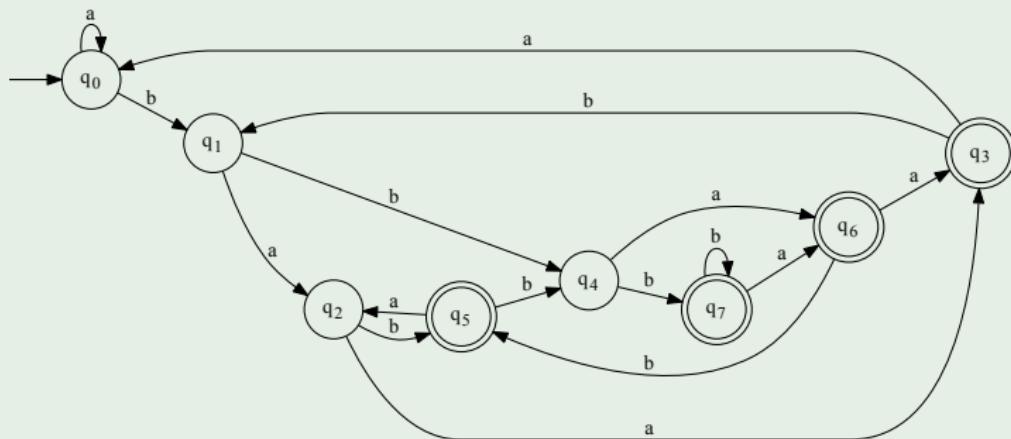

Selected Solutions

Drawbacks of deterministic automata

Deterministic automata:

- ▶ Transition function δ
 - ▶ exactly one transition from every configuration
- ▶ can be complex even for simple languages

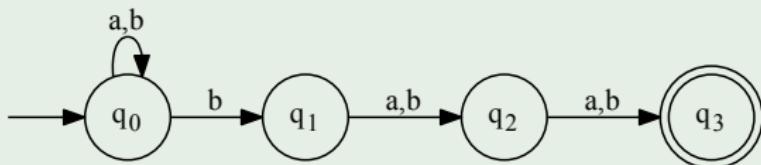

Example (DFA \mathcal{A} for $(a + b)^*b(a + b)(a + b)$)

Non-Determinism

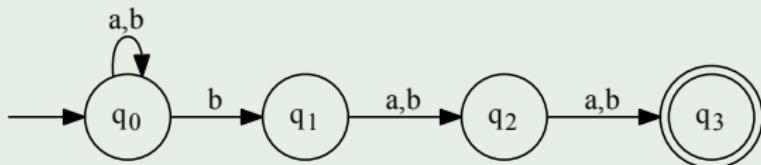

- ▶ FA can be simplified if one input can lead to
 - ▶ one transition,
 - ▶ multiple transitions, or
 - ▶ no transition.
- ▶ Intuitively, such an FA selects its next state from a set of states depending on the current state and the input
 - ▶ and always chooses the “right” one
- ▶ This is called a **non-deterministic finite automaton** (NFA)

Example (NFA \mathcal{B} for $(a + b)^*b(a + b)(a + b)$)

Non-Deterministic automata

Example (Transitions in \mathcal{B})

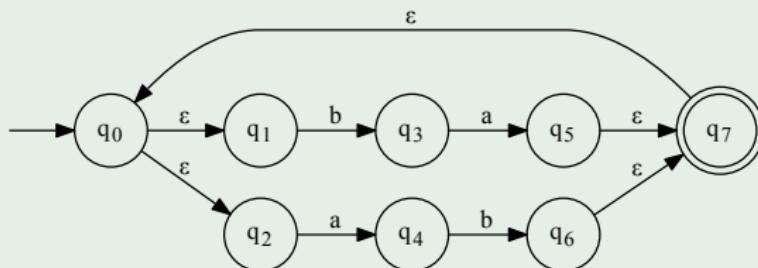

- ▶ In state q_0 with input b , the FA has to “guess” the next state.
- ▶ The string $abab$ can be read in three ways:
 - 1 $q_0 \xrightarrow{a} q_0 \xrightarrow{b} q_0 \xrightarrow{a} q_0 \xrightarrow{b} q_0$ (failure)
 - 2 $q_0 \xrightarrow{a} q_0 \xrightarrow{b} q_0 \xrightarrow{a} q_0 \xrightarrow{b} q_1$ (failure)
 - 3 $q_0 \xrightarrow{a} q_0 \xrightarrow{b} q_1 \xrightarrow{a} q_2 \xrightarrow{b} q_3$ (success)
- ▶ An NFA accepts an input w if there exists an accepting run on w !

NFA: non-deterministic transitions and ε -transitions

- ▶ Non-deterministic transitions allow an NFA to go to more than one successor state
 - ▶ Instead of a function δ , an NFA has a transition relation Δ
- ▶ An NFA can additionally change its current state without reading an input symbol: $q_1 \xrightarrow{\varepsilon} q_2$.
 - ▶ This is called a spontaneous transition or ε -transition
 - ▶ Thus, Δ is a relation on $Q \times (\Sigma \cup \{\varepsilon\}) \times Q$

Example (NFA with ε -transitions)

NFA: Formal definition

Definition (NFA)

An **NFA** is a quintuple $\mathcal{A} = (Q, \Sigma, \Delta, q_0, F)$ with the following components:

- 1 Q is the finite set of states.
- 2 Σ is the input alphabet.
- 3 Δ is a **relation** over $Q \times (\Sigma \cup \{\varepsilon\}) \times Q$.
- 4 $q_0 \in Q$ is the initial state.
- 5 $F \subseteq Q$ is the set of final states.

Run of a nondeterministic automaton

Definition (Configuration, Run of an NFA)

Let $\mathcal{A} = (Q, \Sigma, \Delta, q_0, F)$ be an NFA.

A **configuration** of \mathcal{A} is a pair (q, w) as for a DFA.

A **run** of \mathcal{A} on a word $w_0 = c_1 \cdot c_2 \cdots c_n$ is a sequence of transitions

$$r = ((q_0, w_0), (q_1, w_1), \dots, (q_m, \varepsilon))$$

such that the following conditions are satisfied:

- ▶ $q_i \in Q$ for all $1 \leq i \leq m$,
- ▶ if r contains the configurations $(q_i, w_i), (q_{i+1}, w_{i+1})$, then
 - ▶ there is a transition $(q_i, c, q_{i+1}) \in \Delta$ with $c \in \Sigma \cup \{\varepsilon\}$
 - ▶ $w_i = c \cdot w_{i+1}$.

The run r is **accepting** if q_m is a final state.

The slightly more complex definition is necessary to handle ε -transitions.

Language recognized by an NFA

Definition (Language recognized by an NFA)

Let $\mathcal{A} = (Q, \Sigma, \Delta, q_0, F)$ be an NFA. The language accepted by \mathcal{A} is

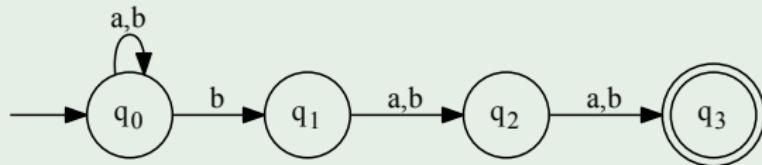

$$L(\mathcal{A}) = \{w \mid \text{there is an accepting run of } \mathcal{A} \text{ on } w\}$$

Note:

- ▶ Only existence of one accepting run is required
- ▶ It does not matter if there are also non-accepting runs on w

Example: NFA definition

Example (Formal definition of \mathcal{B})

$\mathcal{B} = (Q, \Sigma, \Delta, q_0, F)$ with

$$Q = \{q_0, q_1, q_2, q_3\}$$

$$\Sigma = \{a, b\}$$

$$F = \{q_3\}$$

$$\Delta = \{(q_0, a, q_0), (q_0, b, q_0), (q_0, b, q_1), (q_1, a, q_2), (q_1, b, q_2), (q_2, a, q_3), (q_2, b, q_3)\}$$

Δ	a	b	ε
q_0	$\{q_0\}$	$\{q_0, q_1\}$	$\{\}$
q_1	$\{q_2\}$	$\{q_2\}$	$\{\}$
q_2	$\{q_3\}$	$\{q_3\}$	$\{\}$
q_3	$\{\}$	$\{\}$	$\{\}$

Exercise: NFA

Develop an NFA \mathcal{A} whose language $L(\mathcal{A}) \subset \{a, b\}^*$ contains all those words featuring the substring aba. Give:

- ▶ a regular expression representing $L(\mathcal{A})$,
- ▶ a graphical representation of \mathcal{A} ,
- ▶ a formal definition of \mathcal{A} .

Equivalence of DFA and NFA

Theorem (Equivalence of DFA and NFA)

NFAs and DFAs recognize the same class of languages.

- ▶ For every DFA \mathcal{A} there is an NFA \mathcal{B} with $L(\mathcal{A}) = L(\mathcal{B})$.
 - ▶ For every NFA \mathcal{B} there is a DFA \mathcal{A} with $L(\mathcal{B}) = L(\mathcal{A})$.
-
- ▶ The direction DFA to NFA is trivial:
 - ▶ Every DFA is (essentially) an NFA
 - ▶ ...since every function is a relation
 - ▶ What about the other direction?

Equivalence of DFA and NFA

Equivalence of DFAs and NFAs can be shown by transforming

- ▶ an NFA \mathcal{A}
- ▶ into a DFA $\text{det}(\mathcal{A})$ accepting the same language.

Method:

- ▶ states of $\text{det}(\mathcal{A})$ represent **sets of states** of \mathcal{A}
- ▶ a transition from q_1 to q_2 with character c in $\text{det}(\mathcal{A})$ is possible if
 - ▶ in \mathcal{A} there is a transition with c
 - ▶ from **one** of the states that q_1 represents
 - ▶ to **one** of the states that q_2 represents.
- ▶ a state in $\text{det}(\mathcal{A})$ is accepting if it contains an accepting state

To this end, we define three auxiliary functions.

- ▶ ec to compute the ε closure of a state
- ▶ δ^* to compute possible successors of a state
- ▶ $\hat{\delta}$, the new transition function for the generated DFA

Step 1: ε closure of an NFA

The ε closure of a state q contains all states the NFA can change to by means of ε transitions starting from q .

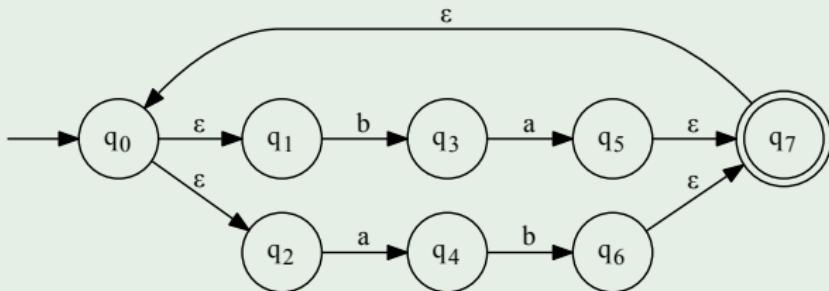

Definition (ε closure)

The function $ec : Q \rightarrow 2^Q$ is the smallest function with the properties:

- ▶ $q \in ec(q)$
- ▶ $p \in ec(q) \wedge (p, \varepsilon, r) \in \Delta \Rightarrow r \in ec(q)$

Example: ε closure

Example

- ▶ $ec(q_0) = \{q_0, q_1, q_2\}$,
- ▶ $ec(q_1) = \{q_1\}$,
- ▶ $ec(q_2) = \{q_2\}$,
- ▶ $ec(q_3) = \{q_3\}$,
- ▶ $ec(q_4) = \{q_4\}$,
- ▶ $ec(q_5) = \{q_5, q_7, q_0, q_1, q_2\}$,
- ▶ $ec(q_6) = \{q_6, q_7, q_0, q_1, q_2\}$,
- ▶ $ec(q_7) = \{q_7, q_0, q_1, q_2\}$.

Step 2: Successor state function for NFAs

The function δ^* maps

- ▶ a pair (q, c)
- ▶ to the set of **all** states the NFA can change to from q with c
- ▶ followed by any number of ε transitions.

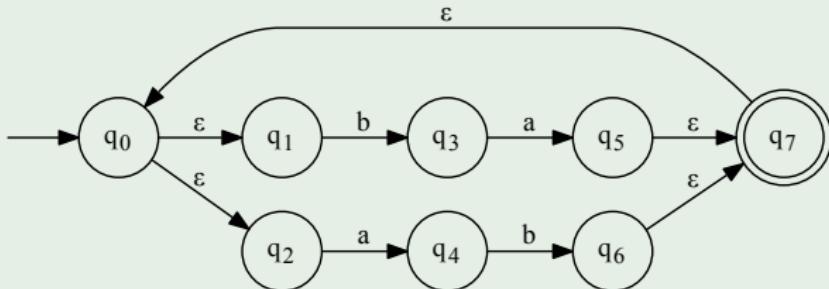

Definition (Successor state function)

The function $\delta^* : Q \times \Sigma \rightarrow 2^Q$ is defined as follows:

$$\delta^*(q, c) = \bigcup_{\substack{r \in Q: \\ (q, c, r) \in \Delta}} ec(r)$$

Example: successor state function

Example

$$\delta^*(q, c) = \bigcup_{r \in Q: (q, c, r) \in \Delta} ec(r)$$

- ▶ $\delta^*(q_0, a) = \{\},$
- ▶ $\delta^*(q_1, b) = \{q_3\},$
- ▶ $\delta^*(q_3, a) = \{q_5, q_7, q_0, q_1, q_2\},$
- ▶ ...

Step 3: extended transition function

The function $\hat{\delta}$ maps

- ▶ a pair (M, c) consisting of a set of states M and a character c
- ▶ to the set N of states that are reachable from any state of M via Δ by reading the character c
- ▶ possibly followed by ε transitions.

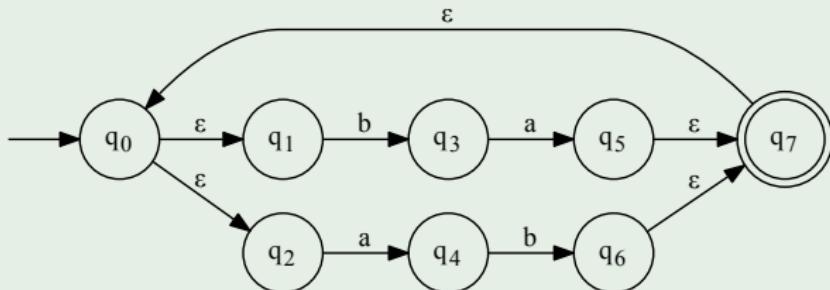

Definition (Extended transition function)

The function $\hat{\delta} : 2^Q \times \Sigma \rightarrow 2^Q$ is defined as follows:

$$\hat{\delta}(M, c) = \bigcup_{q \in M} \delta^*(q, c).$$

Example: extended transition function

Example

- ▶ $\delta^*(q_0, a) = \{\}$
- ▶ $\delta^*(q_1, b) = \{q_3\}$
- ▶ $\delta^*(q_3, a) = \{q_5, q_7, q_0, q_1, q_2\}$
- ▶ \dots
- ▶ $\hat{\delta}(\{q_0, q_1, q_2\}, a) = \{q_4\}$
- ▶ $\hat{\delta}(\{q_3\}, a) = \{q_5, q_7, q_0, q_1, q_2\}$
- ▶ $\hat{\delta}(\{q_3\}, b) = \{\}$
- ▶ \dots

Equivalence of DFA and NFA: formal definition

Using the three steps, we can define $\text{det}(\mathcal{A})$.

Definition

For an NFA $\mathcal{A} = (Q, \Sigma, \Delta, q_0, F)$, the **deterministic** Automaton $\text{det}(\mathcal{A})$ is defined as

$$(2^Q, \Sigma, \hat{\delta}, ec(q_0), \hat{F})$$

with $\hat{F} = \{M \in 2^Q \mid M \cap F \neq \{\}\}$.

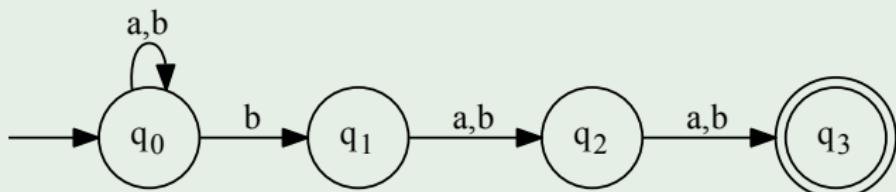

The set of final states \hat{F} is the set of all subsets of Q containing a final state.

Remark

In practice, we use a more efficient stepwise construction that only builds the *reachable* states, not all of 2^Q !

Example: transformation into DFA

Example (NFA \mathcal{B} for $(a + b)^*b(a + b)(a + b)$)

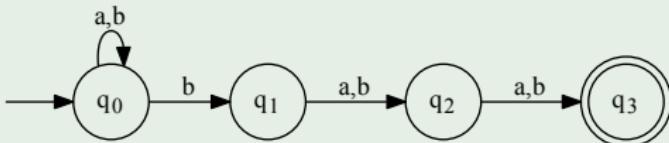

$$\begin{array}{rcl} \mathcal{B} & = & (\{q_0, q_1, q_2, q_3\}, \{a, b\}, \Delta, q_0, \{q_3\}) \\ \text{det}(\mathcal{B}) & = & (\hat{Q}, \{a, b\}, \hat{\delta}, S_0, \hat{F}) \end{array}$$

- Initial state: $S_0 := ec(q_0) = \{q_0\}$

Example: transformation into DFA (cont')

Example

- ▶ $\hat{\delta}(S_0, a) = \{q_0\} = S_0$
- ▶ $\hat{\delta}(S_0, b) = \{q_0, q_1\} =: S_1$
- ▶ $\hat{\delta}(S_1, a) = \{q_0, q_2\} =: S_2$
- ▶ $\hat{\delta}(S_1, b) = \{q_0, q_1, q_2\} =: S_4$
- ▶ $\hat{\delta}(S_2, a) = \{q_0, q_3\} =: S_3$
- ▶ $\hat{\delta}(S_2, b) = \{q_0, q_1, q_3\} =: S_5$
- ▶ $\hat{\delta}(S_4, a) = \{q_0, q_2, q_3\} =: S_6$
- ▶ $\hat{\delta}(S_4, b) = \{q_0, q_1, q_2, q_3\} =: S_7$
- ▶ $\hat{\delta}(S_3, a) = \{q_0\} = S_0$
- ▶ $\hat{\delta}(S_3, b) = \{q_0, q_1\} = S_1$
- ▶ $\hat{\delta}(S_5, a) = \{q_0, q_2\} = S_2$
- ▶ $\hat{\delta}(S_5, b) = \{q_0, q_1, q_2\} = S_4$
- ▶ $\hat{\delta}(S_6, a) = \{q_0, q_3\} = S_3$
- ▶ $\hat{\delta}(S_6, b) = \{q_0, q_1, q_3\} = S_5$
- ▶ $\hat{\delta}(S_7, a) = \{q_0, q_2, q_3\} = S_6$
- ▶ $\hat{\delta}(S_7, b) = \{q_0, q_1, q_2, q_3\} = S_7$

Example: transformation into DFA (cont')

Example

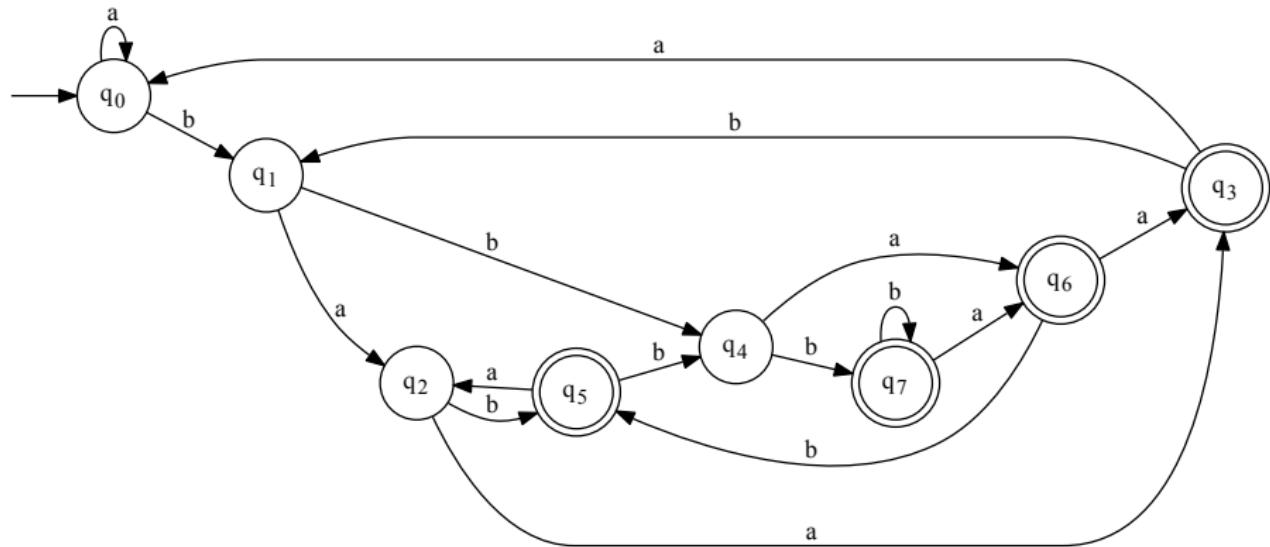

We can now define the DFA $\text{det}(\mathcal{B}) = (\hat{Q}, \Sigma, \hat{\delta}, S_0, \hat{F})$ as follows:

- ▶ the set of states $\hat{Q} = \{S_0, \dots, S_7\}$,
- ▶ the state transition function $\hat{\delta}$ is:

$\hat{\delta}$	S_0	S_1	S_2	S_3	S_4	S_5	S_6	S_7
a	S_0	S_2	S_3	S_0	S_6	S_2	S_3	S_6
b	S_1	S_4	S_5	S_1	S_7	S_4	S_5	S_7

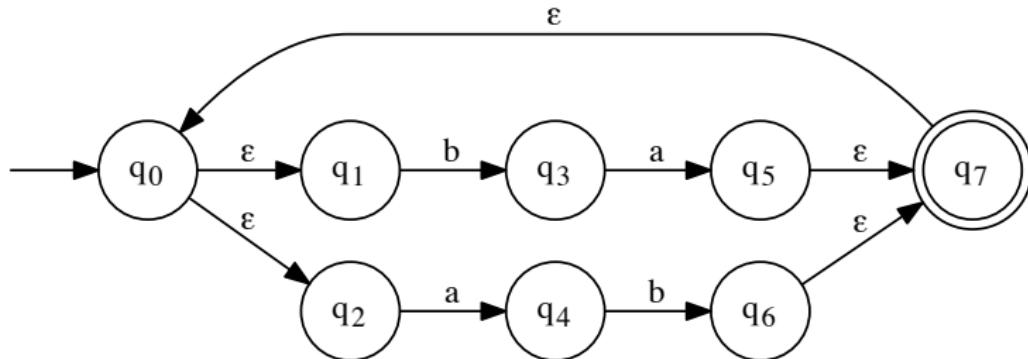

- ▶ and the set of final states $\hat{F} = \{S_3, S_5, S_6, S_7\}$.

Example: transformation into DFA (cont')

Exercise: Transformation into DFA

Given the following NFA \mathcal{A} :

- Determine $\text{det}(\mathcal{A})$.
- Draw $\text{det}(\mathcal{A})$'s graphical representation
- Give a regular expression representing the same language as \mathcal{A} .

 - ▶ Now: Equivalence of NFAs and REs

Transformation of regular expressions into NFAs

- ▶ For a regular expression r , derive NFA $\mathcal{A}(r)$ with $L(\mathcal{A}(r)) = L(r)$.
- ▶ Idea:
 - ▶ Construct NFAs for the elementary REs ($\emptyset, \varepsilon, c \in \Sigma$)
 - ▶ We combine NFAs for subexpressions to generate NFAs for composite REs
- ▶ All NFAs we construct have a number of special properties:
 - ▶ There are no transitions **to the initial state**.
 - ▶ There is only **a single final state**.
 - ▶ There are no transitions **from the final state**.

We can easily achieve this with ε -transitions!

Reminder: Regular Expression

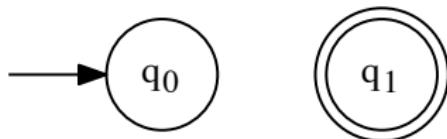

Let Σ be an alphabet.

- ▶ The elementary regular expressions over Σ are:
 - ▶ \emptyset with $L(\emptyset) = \{\}$
 - ▶ ε with $L(\varepsilon) = \{\varepsilon\}$
 - ▶ $c \in \Sigma$ with $L(c) = \{c\}$
- ▶ Let r_1 and r_2 be regular expressions over Σ .
Then the following are also regular expressions over Σ :
 - ▶ $r_1 + r_2$ with $L(r_1 + r_2) = L(r_1) \cup L(r_2)$
 - ▶ $r_1 \cdot r_2$ with $L(r_1 \cdot r_2) = L(r_1) \cdot L(r_2)$
 - ▶ r_1^* with $L(r_1^*) = (L(r_1))^*$

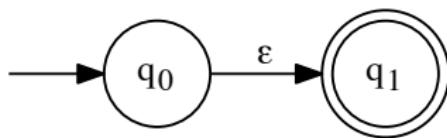

NFAs for elementary REs

Let Σ be the alphabet which r is based on.

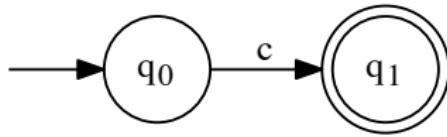

1 $\mathcal{A}(\emptyset) = (\{q_0, q_1\}, \Sigma, \{\}, q_0, \{q_1\})$

2 $\mathcal{A}(\varepsilon) = (\{q_0, q_1\}, \Sigma, \{(q_0, \varepsilon, q_1)\}, q_0, \{q_1\})$

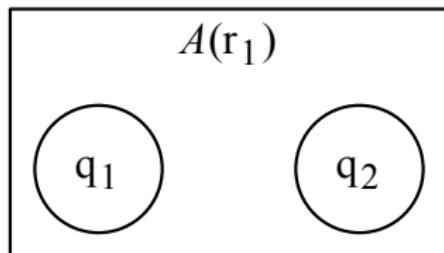

3 $\mathcal{A}(c) = (\{q_0, q_1\}, \Sigma, \{(q_0, c, q_1)\}, q_0, \{q_1\})$ for all $c \in \Sigma$

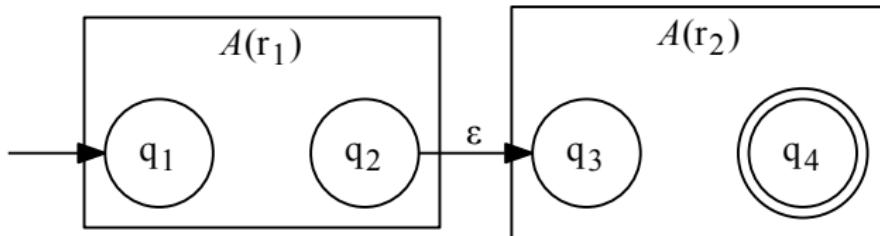

NFAs for composite REs (general)

- ▶ Assume in the following:
 - ▶ $\mathcal{A}(r_1) = (Q_1, \Sigma, \Delta_1, q_1, \{q_2\})$
 - ▶ $\mathcal{A}(r_2) = (Q_2, \Sigma, \Delta_2, q_3, \{q_4\})$
 - ▶ $Q_1 \cap Q_2 = \{\}$
 - ▶ $q_0, q_5 \notin Q_1 \cup Q_2$
- ▶ $\mathcal{A}(r_1)$ is visualised by a square box with two explicit states
 - ▶ The initial state q_1 is on the left
 - ▶ The unique accepting state q_2 on the right
 - ▶ All other states and transitions are implicit
 - ▶ We mark initial/accepting states only for the composite automaton

NFAs for composite REs (concatenation)

4 $\mathcal{A}(r_1 \cdot r_2) = (Q_1 \cup Q_2, \Sigma, \Delta_1 \cup \Delta_2 \cup \{(q_2, \varepsilon, q_3)\}, q_1, \{q_4\})$

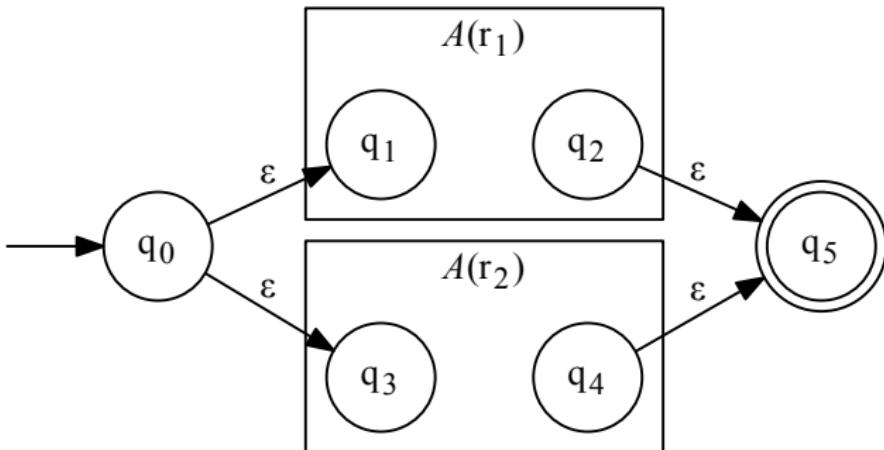

Reminder:

- ▶ $\mathcal{A}(r_1) = (Q_1, \Sigma, \Delta_1, q_1, \{q_2\})$
- ▶ $\mathcal{A}(r_2) = (Q_2, \Sigma, \Delta_2, q_3, \{q_4\})$

NFAs for composite REs (alternatives)

- 5 $\mathcal{A}(r_1 + r_2) = (\{q_0, q_5\} \cup Q_1 \cup Q_2, \Sigma, \Delta, q_0, \{q_5\})$
 $\Delta = \Delta_1 \cup \Delta_2 \cup \{(q_0, \varepsilon, q_1), (q_0, \varepsilon, q_3), (q_2, \varepsilon, q_5), (q_4, \varepsilon, q_5)\}$

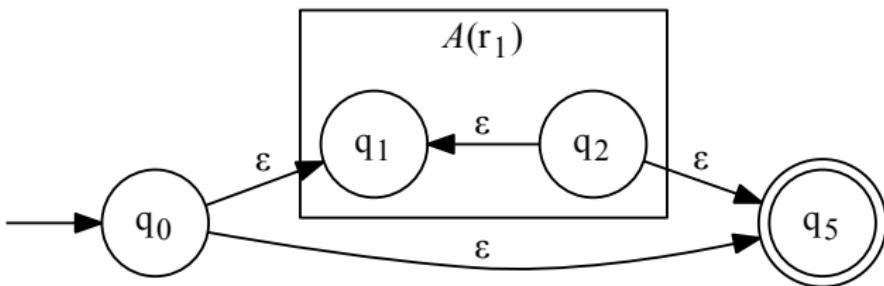

Reminder:

- ▶ $\mathcal{A}(r_1) = (Q_1, \Sigma, \Delta_1, q_1, \{q_2\})$
- ▶ $\mathcal{A}(r_2) = (Q_2, \Sigma, \Delta_2, q_3, \{q_4\})$

NFAs for composite REs (Kleene Star)

- 6 $\mathcal{A}(r_1^*) = (\{q_0, q_5\} \cup Q_1, \Sigma, \Delta, q_0, \{q_5\})$
 $\Delta = \Delta_1 \cup \{(q_0, \varepsilon, q_1), (q_2, \varepsilon, q_1), (q_0, \varepsilon, q_5), (q_2, \varepsilon, q_5)\}$

Reminder:

- ▶ $\mathcal{A}(r_1) = (Q_1, \Sigma, \Delta_1, q_1, \{q_2\})$

Result: NFAs can simulate REs

The previous construction produces for each regular expression r an NFA \mathcal{A} with $L(\mathcal{A}) = L(r)$.

Corollary

Every language described by a regular expression can be accepted by a non-deterministic finite automaton.

Exercise: transformation of RE into NFA

- ▶ Systematically construct an NFA accepting the same language as the regular expression

$$(a + b)a^*b$$

Solution

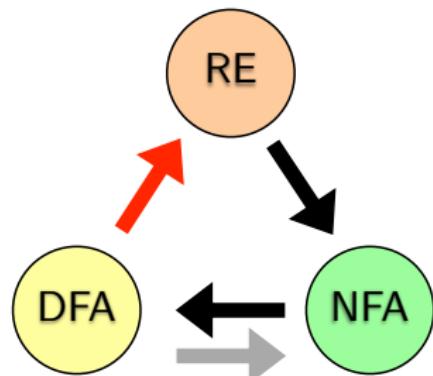

Overview and orientation

- ▶ Claim: NFAs, DFAs and REs all describe the **same** language class
- ▶ Previous transformations:
 - ▶ REs into equivalent NFAs
 - ▶ NFAs into equivalent DFAs
 - ▶ (DFAs to equivalent NFAs)

Todo: convert DFA to equivalent RE

- ▶ Given a DFA \mathcal{A} , derive a regular expression $r(\mathcal{A})$ accepting the same language:

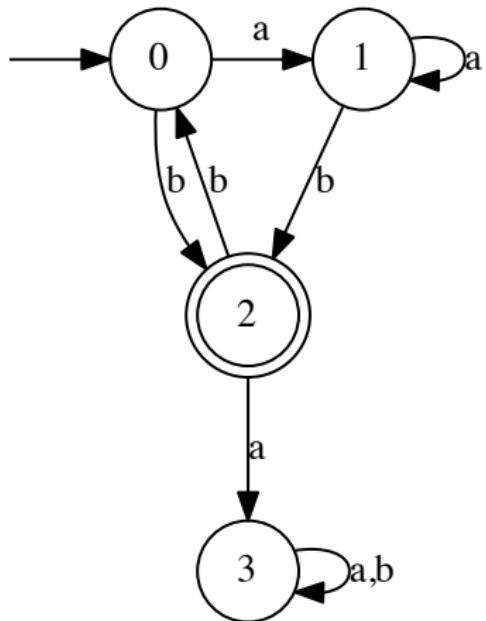

$$L(r(\mathcal{A})) = L(\mathcal{A})$$

Convert DFA into RE

- ▶ Goal: transform DFA $\mathcal{A} = (Q, \Sigma, \delta, q_0, F)$ into RE $r(\mathcal{A})$ with $L(r(\mathcal{A})) = L(\mathcal{A})$
- ▶ Idea:
 - ▶ For each state q generate an **equation** describing the language L_q
 - ▶ that is accepted when **starting from q** ,
 - ▶ depending on the languages accepted at neighbouring states.
 - ▶ Method:
 - ▶ For each transition with c to q' : generate alternative $c \cdot L_{q'}$
 - ▶ For final states: additionally ε
- ▶ Solve the resulting system for L_{q_0}
 - ▶ Result: RE describing $L_{q_0} = L(\mathcal{A})$
- ▶ Convention:
 - ▶ States are named $\{0, 1, \dots, n\}$
 - ▶ Initial state is 0

Convert DFA to RE: Example

- ▶ $L_0 \doteq aL_1 + bL_2$
- ▶ $L_1 \doteq aL_1 + bL_2$
- ▶ $L_2 \doteq aL_3 + bL_0 + \varepsilon$
- ▶ $L_3 \doteq (a + b)L_3$

4 equations, 4 unknowns

What now?

Insert: Arden's Lemma

Lemma:

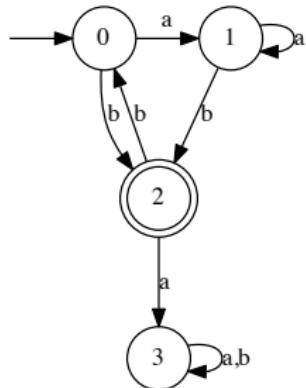

$$\varepsilon \notin L(s) \text{ and } r \doteq sr + t \longrightarrow r \doteq s^*t$$

Compare Arto Salomaa:

$$\varepsilon \notin L(s) \text{ and } r \doteq rs + t \longrightarrow r \doteq ts^*$$

and finite-state
machines*,
Proceedings of
the Second
Annual
Symposium on
Switching
Circuit Theory
and Logical
Design, 1961,
pp. 133–151,
IEEE

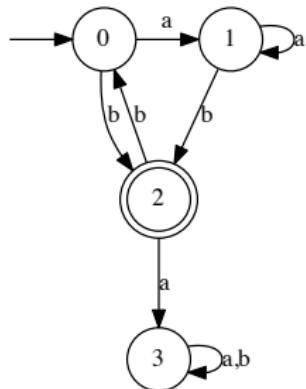

Convert DFA to RE: Example

- ▶ $L_0 \doteq aL_1 + bL_2$
- ▶ $L_1 \doteq aL_1 + bL_2$
- ▶ $L_2 \doteq aL_3 + bL_0 + \varepsilon$
- ▶ $L_3 \doteq (a + b)L_3$

$$\begin{aligned} L_3 &\doteq (a + b)L_3 + \emptyset && [\text{neutral el.}] \\ &\doteq (a + b)^*\emptyset && [\text{Arden}] \\ &\doteq \emptyset && [\text{absorbing el.}] \\ L_2 &\doteq a\emptyset + bL_0 + \varepsilon && [\text{replace } L_3] \\ &\doteq \emptyset + bL_0 + \varepsilon && [\text{absorbing el.}] \\ &\doteq bL_0 + \varepsilon && [\text{neutral el.}] \\ L_1 &\doteq aL_1 + b(bL_0 + \varepsilon) && [\text{replace } L_2] \\ &\doteq a^*b(bL_0 + \varepsilon) && [\text{Arden}] \end{aligned}$$

Convert DFA to RE: Example (continued)

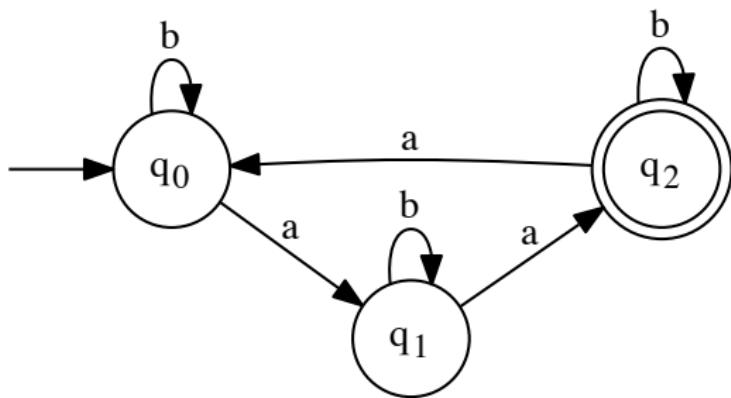

- ▶ $L_0 \doteq aL_1 + bL_2$
- ▶ $L_1 \doteq a^*b(bL_0 + \varepsilon)$
- ▶ $L_2 \doteq bL_0 + \varepsilon$
- ▶ $L_3 \doteq \emptyset$

$$\begin{aligned} L_0 &\doteq a(a^*b(bL_0 + \varepsilon)) + b(bL_0 + \varepsilon) && [\text{replace } L_1, L_2] \\ &\doteq aa^*bbL_0 + aa^*b + bbL_0 + b && [\text{dist.}] \\ &\doteq (aa^*bb + bb)L_0 + aa^*b + b && [\text{comm., dist.}] \\ &\doteq (aa^*bb + bb)^*(aa^*b + b) && [\text{Arden}] \\ &\doteq ((aa^* + \varepsilon)bb)^*((aa^* + \varepsilon)b) && [\text{dist.}] \\ &\doteq (a^*bb)^*(a^*b) && [rr^* + \varepsilon \doteq r^*] \end{aligned}$$

Therefore: $L(\mathcal{A}) = L((a^*bb)^*(a^*b))$

Exercise: conversion from DFA to RE

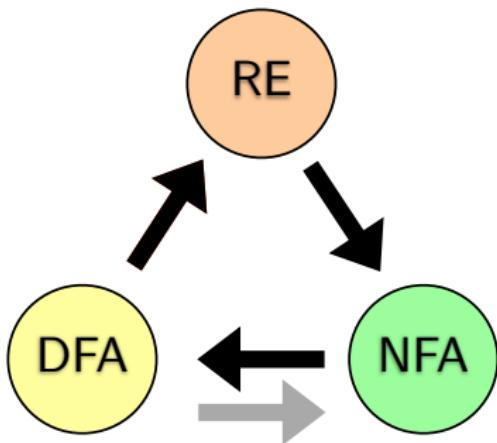

Transform the following DFA into a regular expression accepting the same language:

Resume: Finite automata and regular expressions

- ▶ We have learned how to convert
 - ▶ REs to equivalent NFAs
 - ▶ NFAs to equivalent DFAs
 - ▶ (DFAs to equivalent NFAs)
 - ▶ DFAs to equivalent REs

REs, NFAs and DFAs describe the same class of languages – regular languages!

Efficient Automata: Minimisation of DFAs

Given the DFA

$$\mathcal{A} = (Q, \Sigma, \delta, q_0, F),$$

we want to derive a DFA

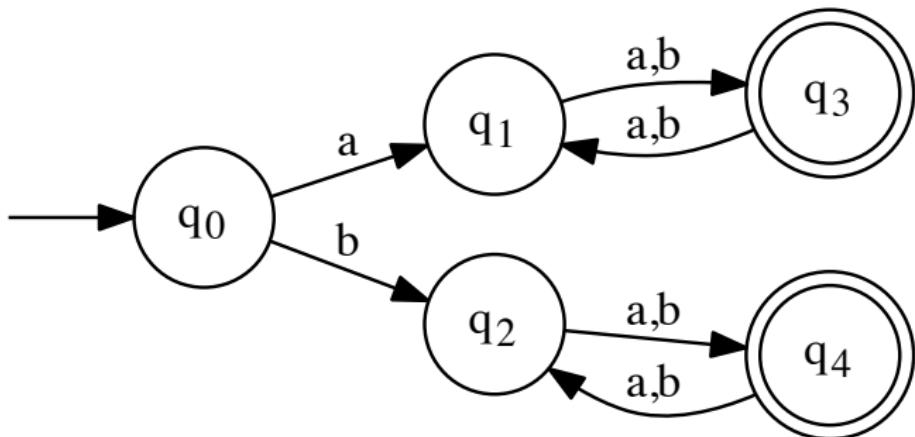

$$\mathcal{A}^- = (Q^-, \Sigma, \delta^-, q_0, F^-),$$

accepting the same language:

$$L(\mathcal{A}) = L(\mathcal{A}^-)$$

for which the **number of states** (elements of Q^-) is **minimal**, i.e. there is no DFA accepting $L(\mathcal{A})$ with fewer states.

Minimisation of DFAs: example/exercise

How small can we make it?

Minimisation of DFAs

Idea: For a DFA $\mathcal{A} = (Q, \Sigma, \delta, q_0, F)$, identify pairs of necessarily distinct states

- ▶ Base case: Two states p, q are necessarily distinct if:
 - ▶ one of them is accepting, the other is not accepting
- ▶ Inductive case: Two states p, q are necessarily distinct if
 - ▶ there is a $c \in \Sigma$ such that $\delta(p, c) = p', \delta(q, c) = q'$
 - ▶ and p', q' are already necessarily distinct

Definition (Necessarily distinct states)

For a DFA $\mathcal{A} = (Q, \Sigma, \delta, q_0, F)$, V is the smallest set of pairs with

- ▶ $\{(p, q) \in (Q \times Q) \mid p \in F, q \notin F\} \subseteq V$
- ▶ $\{(p, q) \in (Q \times Q) \mid p \notin F, q \in F\} \subseteq V$
- ▶ if $\delta(p, c) = p', \delta(q, c) = q', (p', q') \in V$ for some $c \in \Sigma$,
then $(p, q) \in V$.

Minimisation of DFAs

- 1 Initialize V with all those pairs for which one member is a final state and the other is not:

$$V = \{(p, q) \in Q \times Q \mid (p \in F \wedge q \notin F) \vee (p \notin F \wedge q \in F)\}.$$

- 2 While there exists
 - ▶ a new pair of states (p, q) and a symbol c
 - ▶ such that the states $\delta(p, c)$ and $\delta(q, c)$ are necessarily distinct,
 - ▶ add this pair and its inverse to V :

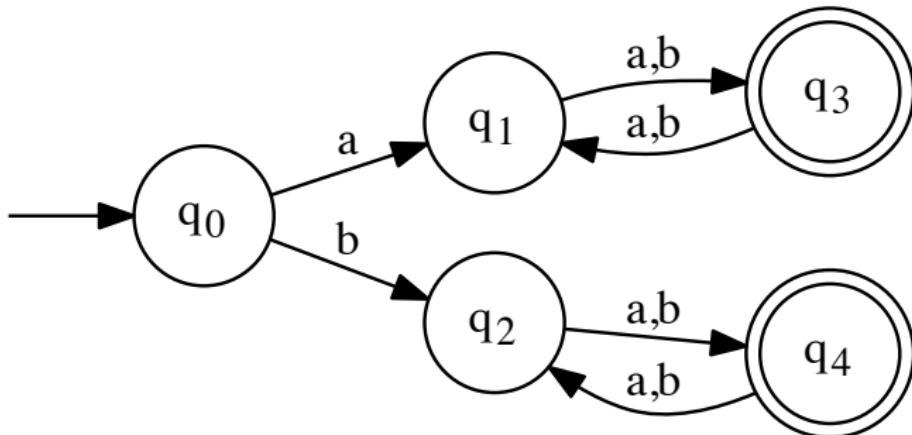

```
while (exists(p, q) in Q x Q exists(c in Sigma | (delta(p, c), delta(q, c)) in V) and (p, q) not in V)
{
    V = V union {(p, q), (q, p)}
}
```

Minimisation of DFAs: merging States

- ▶ If there is a pair of states (p, q) such that for every word $w \in \Sigma^*$
 - ▶ reading w results in indistinguishable successor states,
 - ▶ then p and q are indistinguishable.
 $(p, q) \notin V \Rightarrow \forall w \in \Sigma^* : \delta(p, w)$ and $\delta(q, w)$ are indistinguishable.
- ▶ Indistinguishable states p, q can be merged
 - ▶ Replace all transitions to p by transitions to q
 - ▶ Remove p
- ▶ This process can be iterated to identify and merge all indistinguishable pairs of states

Minimisation of DFAs: example

We want to minimize this DFA with 5 states:

Minimisation of DFAs: example (cont.)

This is the formal definition of the DFA:

$$\mathcal{A} = (Q, \Sigma, \delta, q_0, F)$$

with

- 1 $Q = \{q_0, q_1, q_2, q_3, q_4\}$
- 2 $\Sigma = \{\text{a}, \text{b}\}$
- 3 $\delta = \dots$ (skipped to save space, see graph)
- 4 $F = \{q_3, q_4\}$

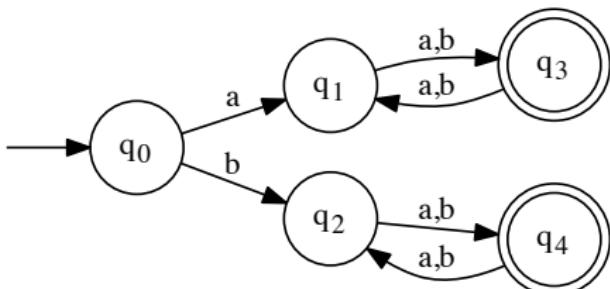

Represent the set V by means of a two-dimensional table with

- ▶ the elements of Q as columns and rows
- ▶ the elements of V are marked with \times
- ▶ pairs that are definitely **not** members of V are marked with \circ

Minimisation of DFAs: example (cont.)

- 1 the initial state of V is obtained by using $F = \{q_3, q_4\}$ and $Q \setminus F = \{q_0, q_1, q_2\}$:

	q_0	q_1	q_2	q_3	q_4
q_0				×	×
q_1				×	×
q_2				×	×
q_3	×	×	×		
q_4	×	×	×		

Minimisation of DFAs: example (cont.)

- 2 The elements of $\{(q_i, q_i) \mid i \in \{0, \dots, 4\}\}$ are not contained in V since every state is indistinguishable from itself:

	q_0	q_1	q_2	q_3	q_4
q_0	o			x	x
q_1		o		x	x
q_2			o	x	x
q_3	x	x	x	o	
q_4	x	x	x		o

There are eight remaining empty fields. Since the table is symmetric, four pairs of states have to be checked.

Minimisation of DFAs: example (cont.)

- 3 Check the transitions of every remaining state-pair for every letter.

- 1 $\delta(q_0, a) = q_1; \delta(q_1, a) = q_3; (q_1, q_3) \in V \rightarrow (q_0, q_1), (q_1, q_0) \in V$
- 2 $\delta(q_0, a) = q_1; \delta(q_2, a) = q_4; (q_1, q_4) \in V \rightarrow (q_0, q_2), (q_2, q_0) \in V$
- 3 $\delta(q_1, a) = q_3; \delta(q_2, a) = q_4; (q_3, q_4) \notin V$ (as of yet)
 $\delta(q_1, b) = q_3; \delta(q_2, b) = q_4; (q_3, q_4) \notin V$ (as of yet)
- 4 $\delta(q_3, a) = q_1; \delta(q_4, a) = q_2; (q_1, q_2) \notin V$ (as of yet)
 $\delta(q_3, b) = q_1; \delta(q_4, b) = q_2; (q_1, q_2) \notin V$ (as of yet)

Minimisation of DFAs: example (cont.)

- 4 Mark the newly found distinguishable pairs with \times :

	q_0	q_1	q_2	q_3	q_4
q_0	o	\times	\times	\times	\times
q_1	\times	o		\times	\times
q_2	\times		o	\times	\times
q_3	\times	\times	\times	o	
q_4	\times	\times	\times		o

Two pairs remain to be checked.

Minimisation of DFAs: example (cont.)

- 5 Check the remaining pairs.
- 6 Since no additional distinguishable state pairs are found, fill empty cells with \circ :

	q_0	q_1	q_2	q_3	q_4
q_0	\circ	\times	\times	\times	\times
q_1	\times	\circ	\circ	\times	\times
q_2	\times	\circ	\circ	\times	\times
q_3	\times	\times	\times	\circ	\circ
q_4	\times	\times	\times	\circ	\circ

From the table, we can derive the following indistinguishable state pairs (omitting trivial and symmetric ones):

- ▶ (q_1, q_2) ,
- ▶ (q_3, q_4) .

Minimisation of DFAs: example (cont.)

- ▶ This is the minimized DFA after merging indistinguishable states:

Minimisation of DFAs: exercise

Derive a minimal DFA accepting the language

$$L(a(ba)^*).$$

Solve the exercise in three steps:

- 1 Derive an NFA accepting L .
- 2 Transform the NFA into a DFA.
- 3 Minimize the DFA.

Uniqueness of minimal DFA

Theorem (The minimal DFA is unique)

*Assume an arbitrary regular language L . Then there is a unique (up to the renaming of states) **minimal** DFA \mathcal{A} with $L(\mathcal{A}) = L$.*

- ▶ States can easily be systematically renamed to make equivalent minimal automata strictly equal
- ▶ The unique minimal DFA for L can be constructed by minimizing an arbitrary DFA that accepts L

Selected Solutions

Equivalence of regular expressions

- ▶ Different regular expressions can describe the **same language**
- ▶ **Algebraic transformation rules** can be used to prove equivalence
 - ▶ requires human interaction
 - ▶ can be very difficult
 - ▶ non-equivalence cannot be shown
- ▶ Now: straight-forward algorithm proving equivalence of REs based on FA
- ▶ The algorithm is described in the textbook by John E. Hopcroft, Rajeev Motwani, Jeffrey D. Ullman: *Introduction to Automata Theory, Languages, and Computation (3rd edition)*, 2007 (and earlier editions)

Equivalence of regular expressions: algorithm

- Given the REs r_1 and r_2 , derive NFAs \mathcal{A}_1 and \mathcal{A}_2 accepting their respective languages:

$$L(r_1) = L(\mathcal{A}_1) \quad \text{and} \quad L(r_2) = L(\mathcal{A}_2).$$

- Transform the NFAs \mathcal{A}_1 and \mathcal{A}_2 into the DFAs \mathcal{D}_1 and \mathcal{D}_2 .
- Minimize the DFAs \mathcal{D}_1 and \mathcal{D}_2 yielding the DFAs \mathcal{M}_1 and \mathcal{M}_2 .
- $r_1 \doteq r_2$ holds iff \mathcal{M}_1 and \mathcal{M}_2 are identical (modulo renaming of states)

Note: If equivalence can be shown in any intermediate stage of the algorithm, this is sufficient to prove $r_1 \doteq r_2$ (e.g. if $\mathcal{A}_1 = \mathcal{A}_2$).

Exercise: Equivalence of regular expressions

Reusing an exercise from an earlier section, prove the following equivalence (by conversion to minimal DFAs):

$$10(10)^* \doteq 1(01)^*0$$

Non-regular languages

For some simple languages, there is no obvious FA:

Example (Naive automaton \mathcal{A} for $L = \{a^n b^n \mid n \in \mathbb{N}\}$)

\mathcal{A} has an infinite number of states:

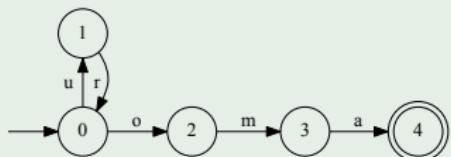

- ▶ Is there a better solution?
- ▶ If no, how can this be shown?

Pumping Lemma: Idea

- 1 Every regular language L is accepted by a finite Automaton \mathcal{A}_L .
- 2 If L contains arbitrarily long words, then \mathcal{A}_L must contain a cycle.
 - ▶ L contains arbitrarily long words iff L is infinite.
- 3 If \mathcal{A}_L contains a cycle, then the cycle can be traversed arbitrarily often (and the resulting word will be accepted).

Example (Cyclic Automaton \mathcal{C})

- ▶ \mathcal{C} accepts uroma
- ▶ \mathcal{C} also accepts ururur...oma

The Pumping Lemma

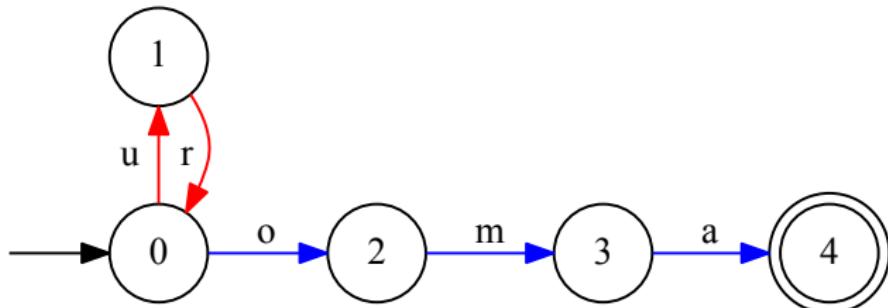

Lemma

Let L be a regular language.

Then there exists a $k \in \mathbb{N}$ such that for every word $s \in L$ with $|s| \geq k$ the following holds:

- 1 $\exists u, v, w \in \Sigma^*(s = u \cdot v \cdot w)$,
i.e. s consists of *prolog* u , *cycle* v and *epilog* w ,
- 2 $v \neq \varepsilon$,
i.e. the cycle has a *length of at least 1*,
- 3 $|u \cdot v| \leq k$,
i.e. prolog and cycle combined have a *length of at most k* ,
- 4 $\forall h \in \mathbb{N}(u \cdot v^h \cdot w \in L)$,
i.e. an *arbitrary number of cycle transitions* results in a word of the language L .

The Pumping Lemma visualised

- ▶ \mathcal{C} has 5 states $k = 5$
- ▶ $urom\alpha$ has 5 letters $s = urom\alpha$
- ▶ There is a segmentation $s = u \cdot v \cdot w$ $u = \varepsilon$ $v = ur$ $w = oma$
- ▶ such that $|v| \neq \varepsilon$ $v = ur$
- ▶ and $|u \cdot v| \leq k$ $|\varepsilon \cdot ur| = 2 \leq 5$
- ▶ and $\forall h \in \mathbb{N}(u \cdot v^h \cdot w \in L(\mathcal{C}))$ $(ur)^*oma \subseteq L(\mathcal{C})$

Pumping Lemma: Idea II

- ▶ If L is regular, then there exists a DFA \mathcal{A} with $L = L(\mathcal{A})$
- ▶ That DFA has (e.g.) $k - 1$ states
- ▶ For every $w \in L$ with $|w| \geq k$ the automaton must execute a loop
- ▶ u is the word read to the first state of the loop
- ▶ v is the word read in the loop
- ▶ w is the word read after the loop
- ▶ ... so every word that traverses v zero or multiple times is also accepted by \mathcal{A}

Exercise: The Pumping Game

Play the pumping game at <http://weitz.de/pump/>.

Using the Pumping Lemma

- ▶ The Pumping Lemma describes a property of **regular** languages
 - ▶ *If L is regular, then some words can be pumped up.*
- ▶ Goal: proof of **irregularity** of a language
 - ▶ *If L has property X , then L is not regular.*
- ▶ How can the Pumping Lemma help?

Theorem (Contraposition)

$$A \rightarrow B \quad \Leftrightarrow \quad \neg B \rightarrow \neg A$$

Contraposition of the Pumping Lemma

The Pumping Lemma in formal logic:

$$\text{reg}(L) \rightarrow \exists k \in \mathbb{N} \forall s \in L : (|s| \geq k \rightarrow \\ \exists u, v, w : (s = u \cdot v \cdot w \wedge v \neq \varepsilon \wedge |u \cdot v| \leq k \wedge \\ \forall h \in \mathbb{N} : (u \cdot v^h \cdot w \in L)))$$

Contraposition of the PL:

$$\neg(\exists k \in \mathbb{N} \forall s \in L(|s| \geq k \rightarrow \\ \exists u, v, w(s = u \cdot v \cdot w \wedge v \neq \varepsilon \wedge |u \cdot v| \leq k \wedge \\ \forall h \in \mathbb{N}(u \cdot v^h \cdot w \in L)))) \rightarrow \neg\text{reg}(L)$$

After pushing negation inward and doing some propositional transformations:

$$\forall k \in \mathbb{N} \exists s \in L(|s| \geq k \wedge \\ \forall u, v, w(s = u \cdot v \cdot w \wedge v \neq \varepsilon \wedge |u \cdot v| \leq k \rightarrow \\ \exists h \in \mathbb{N}(u \cdot v^h \cdot w \notin L))) \rightarrow \neg\text{reg}(L)$$

What does it mean?

$$\begin{aligned} & \forall k \in \mathbb{N} \exists s \in L (|s| \geq k \wedge \\ & \forall u, v, w (s = u \cdot v \cdot w \wedge v \neq \varepsilon \wedge |u \cdot v| \leq k \rightarrow \\ & \quad \exists h \in \mathbb{N} (u \cdot v^h \cdot w \notin L))) \rightarrow \neg \text{reg}(L) \end{aligned}$$

If for every number k there is a word s with length at least k and for every segmentation $u \cdot v \cdot w$ of s (with $v \neq \varepsilon$ and $|u \cdot v| \leq k$) there is a number h such that $u \cdot v^h \cdot w$ does not belong to L , then L is not regular.

Proving Irregularity for a Language

We have to show:

- ▶ For **every** natural number k
- ▶ For an unspecified arbitrary natural number k
- ▶ **there is** a word $s \in L$ that is longer than k
- ▶ such that **every** segmentation $u \cdot v \cdot w = s$ with $|u \cdot v| \leq k$ and $|v| \neq \varepsilon$
- ▶ **can** be pumped up into a word $u \cdot v^h \cdot w \notin L$.

Example ($L = a^n b^n$)

- ▶ Choose $s = a^k b^k$. It follows:

$$s = \underbrace{a^i}_u \cdot \underbrace{a^j}_v \cdot \underbrace{a^\ell \cdot b^k}_w$$

- ▶ $i + j + \ell = k$
- ▶ since $|u \cdot v| \leq k$ holds, u and v consist only of a s
- ▶ $v \neq \varepsilon$ implies $j \geq 1$

- ▶ Choose $h = 0$. It follows:

- ▶ $u \cdot v^h \cdot w = u \cdot w = a^{i+\ell} b^k$
- ▶ $j \geq 1$ implies $i + \ell < k$
- ▶ $a^{i+\ell} b^k \notin L$

Regarding quantifiers

Four quantifiers:

- ▶ In the lemma:

$$\exists k \forall s \exists u, v, w \forall h (u \cdot v^h \cdot w \in L)$$

- ▶ To show irregularity:

$$\forall k \exists s \forall u, v, w \exists h (u \cdot v^h \cdot w \notin L)$$

To do:

- 1 Find a word s depending on the length k .
- 2 Find an h depending on the segmentation $u \cdot v \cdot w$.
- 3 Prove that $u \cdot v^h \cdot w \notin L$ holds.

Exercise: $a^n b^m$ with $n < m$

Use the pumping lemma to show that

$$L = \{a^n b^m \mid n < m\}$$

is not regular.

Reminder:

- 1 Find a word s depending on the length k .
- 2 Find an h depending on the segmentation $u \cdot v \cdot w$.
- 3 Prove that $u \cdot v^h \cdot w \notin L$ holds.

Solution

Challenging exercise / homework

Let L be the number containing all words of the form a^p where p is a prime number:

$$L = \{a^p \mid p \in \mathbb{P}\}.$$

Prove that L is not a regular language.

Hint: let $h = p + 1$

Solution

Practical relevance of irregularity

Finite automata cannot **count** arbitrarily high.

Examples (Nested dependencies)

C for every { there is a }

XML for every <token> there is a </token>

LATEX for every \begin{env} there is a \end{env}

German for every subject there is a predicate

Erinnern Sie sich,
wie der Krieger,
der die Botschaft,
die den Sieg,
den die Griechen bei Marathon
errungen hatten,
verkündete,
brachte,
starb!

Pumping Lemma: Summary

- ▶ Every regular language is accepted by a DFA \mathcal{A} (with k states).
- ▶ Pumping lemma: words with at least k letters can be **pumped up**.
- ▶ If it is possible to pump up a word $w \in L$ and obtain a word $w' \notin L$, then L is **not regular**.
 - ▶ Make sure to handle quantifiers correctly!
- ▶ Practical relevance
 - ▶ FAs cannot **count arbitrarily high**.
 - ▶ **Nested structures** are not regular.
 - ▶ programming languages
 - ▶ natural languages
 - ▶ More powerful tools are needed to handle these languages.

Selected Solutions

Regular languages: Closure properties

Reminder:

- ▶ **Formal languages** are sets of words (over a finite alphabet)
- ▶ A formal language L is a *regular language* if any of the following holds:
 - ▶ There exists an NFA \mathcal{A} with $L(\mathcal{A}) = L$
 - ▶ There exists a DFA \mathcal{A} with $L(\mathcal{A}) = L$
 - ▶ There exists a regular expression r with $L(r) = L$
 - ▶ There exists a regular grammar G with $L(G) = L$
- ▶ Pumping lemma: not all languages are regular

Question

**What can we do to regular languages
and be sure the result is still regular?**

Closure properties (Question)

Question: If L_1 and L_2 are regular languages, does the same hold for

- | | |
|--|-------------------------------|
| $L_1 \cup L_2 ?$ | (closure under union) |
| $L_1 \cap L_2 ?$ | (closure under intersection) |
| $L_1 \cdot L_2 ?$ | (closure under concatenation) |
| $\overline{L_1}$, i.e. $\Sigma^* \setminus L$? | (closure under complement) |
| $L_1^* ?$ | (closure under Kleene-star) |

Meta-Question: How do we answer these questions?

Closure properties (Theorem)

Theorem

Let L_1 and L_2 be regular languages. Then the following languages are also regular:

- ▶ $L_1 \cup L_2$
- ▶ $L_1 \cap L_2$
- ▶ $L_1 \cdot L_2$
- ▶ $\overline{L_1}$, i.e. $\Sigma^* \setminus L$
- ▶ L_1^*

Proof.

Idea: using (disjoint) finite automata for L_1 and L_2 , construct an automaton for the different languages above.

Closure under union, concatenation, and Kleene-star

We use the same construction that was used to generate NFAs for regular expressions:

Let \mathcal{A}_{L_1} and \mathcal{A}_{L_2} be automata for L_1 and L_2 .

$L_1 \cup L_2$ new initial and final states,

ε -transitions to initial/final states of \mathcal{A}_{L_1} and \mathcal{A}_{L_2}

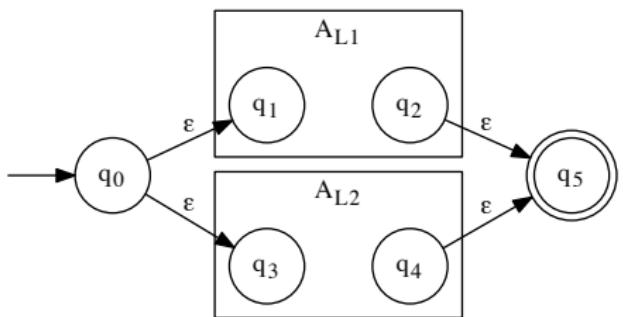

$L_1 \cdot L_2$ ε -transition from final state of \mathcal{A}_{L_1} to initial state of \mathcal{A}_{L_2}

- $(L_1)^*$
 - ▶ new initial and final states (with ε -transitions),
 - ▶ ε -transitions from the original final states to the original initial state,
 - ▶ ε -transition from the new initial to the new final state.

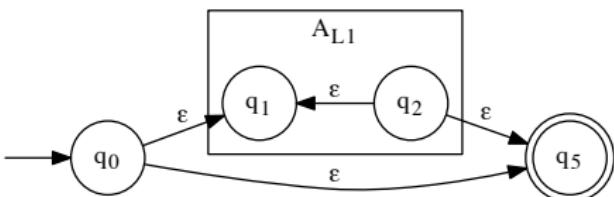

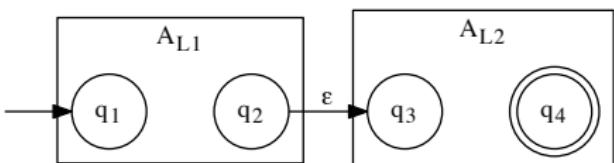

Visual refresher

$L_1 \circ L_2$

$L_1 \cup L_2$

L_1^*

Closure under intersection

Let $\mathcal{A}_{L_1} = (Q_1, \Sigma, \delta_1, q_{0_1}, F_1)$ and $\mathcal{A}_{L_2} = (Q_2, \Sigma, \delta_2, q_{0_2}, F_2)$ be DFAs for L_1 and L_2 .

An automaton $L = (Q, \Sigma, \delta, q_0, F)$ for $\mathcal{A}_{L_1} \cap \mathcal{A}_{L_2}$ can be generated as follows:

- ▶ $Q = Q_1 \times Q_2$
- ▶ $\delta((q_1, q_2), a) = (\delta_1(q_1, a), \delta_2(q_2, a))$ for all $q_1 \in Q_1, q_2 \in Q_2, a \in \Sigma$
- ▶ $q_0 = (q_{0_1}, q_{0_2})$
- ▶ $F = F_1 \times F_2$

This **product automaton**

- ▶ starts in state that corresponds to initial states of \mathcal{A}_{L_1} and \mathcal{A}_{L_2} ,
- ▶ simulates simultaneous processing in both automata
- ▶ accepts if both \mathcal{A}_{L_1} and \mathcal{A}_{L_2} accept.

Exercise: Product automaton

Generate automata for

- ▶ $L_1 = \{w \in \{0, 1\}^* \mid |w|_1 \text{ is divisible by } 2\}$
- ▶ $L_2 = \{w \in \{0, 1\}^* \mid |w|_1 \text{ is divisible by } 3\}$

Then generate an automaton for $L_1 \cap L_2$.

[Solution](#)

[End lecture 8](#)

Closure under complement

Theorem (Closure under complement)

Let L be a regular language over Σ . Then $\bar{L} = \Sigma^* \setminus L$ is regular.

Let $\mathcal{A}_L = (Q, \Sigma, q_0, \delta, F)$ be a DFA for the language L .

Then $\overline{\mathcal{A}_L} = (Q, \Sigma, q_0, \delta, Q \setminus F)$ is an automaton accepting \bar{L} :

- ▶ if $w \in L(\mathcal{A})$ then $\delta'(q_0, w) \in F$, i.e.
 $\delta'(q_0, w) \notin Q \setminus F$, which implies $w \notin L(\overline{\mathcal{A}_L})$.
- ▶ if $w \notin L(\mathcal{A})$ then $\delta'(q_0, w) \notin F$, i.e.
 $\delta'(q_0, w) \in Q \setminus F$, which implies $w \in L(\overline{\mathcal{A}_L})$.

Reminder:

$$\delta' : Q \times \Sigma^* \rightarrow Q$$

$\delta'(q_0, w)$ is the final state of the automaton after processing w

All we have to do is exchange accepting and non-accepting states.

Closure properties: exercise

Show that $L = \{w \in \{a, b\}^* \mid |w|_a = |w|_b\}$ is not regular.

Hint: Use the following:

- ▶ $a^n b^n$ is not regular. (Pumping lemma)
- ▶ $a^* b^*$ is regular. (Regular expression)
- ▶ (one of) the closure properties shown before.

Finite languages and automata

Theorem (Regularity of finite languages)

Every finite language, i.e. every language containing only a finite number of words, is regular.

Proof.

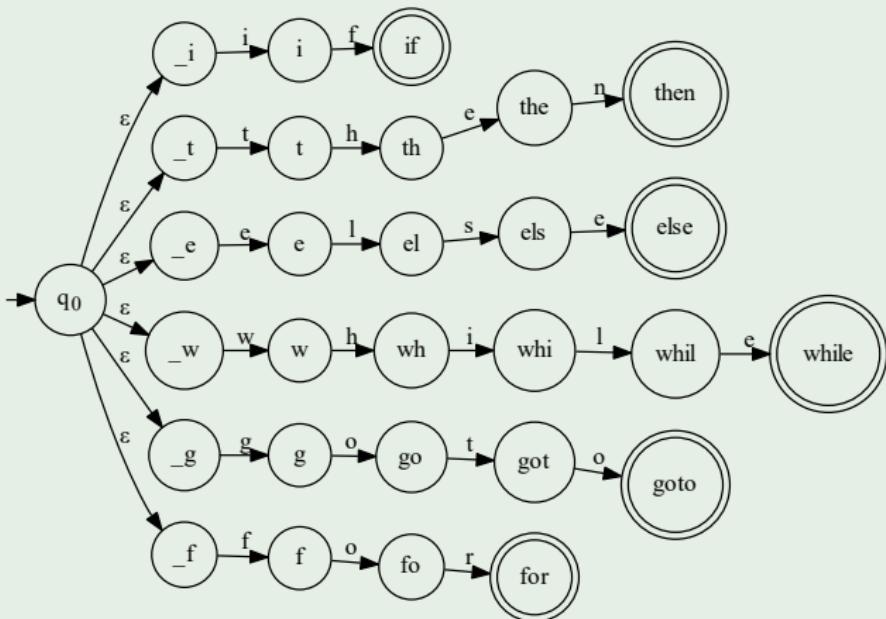

Let $L = \{w_1, \dots, w_n\}$.

- ▶ For each w_i , generate an automaton \mathcal{A}_i with initial state q_{0i} and final state q_{fi} .
- ▶ Let q_0 be a new state, from which there is an ε -transition to each q_{0i} .

Then the resulting automaton, with q_0 as initial state and all q_{fi} as final states, accepts L . □

Example: finite language

Example ($L = \{if, then, else, while, goto, for\}$ over Σ_{ASCII})

Finite languages and regular expressions

Theorem (Regularity of finite languages)

Every finite language is regular.

Alternate proof.

Let $L = \{w_1, w_2, \dots, w_n\}$.

Write L as the regular expression $w_1 + w_2 + \dots + w_n$. □

Corollary

The class of finite languages is characterised by

- ▶ *acyclic NFAs (or DFAs that have no cycles on any path from the initial state to an accepting state)*
- ▶ *regular expressions without Kleene star.*

Decision problems

For regular languages L_1 and L_2 and a word w , answer the following questions:

- | | |
|------------------------------|---------------------|
| Is there a word in L_1 ? | emptiness problem |
| Is w an element of L_1 ? | word problem |
| Is L_1 equal to L_2 ? | equivalence problem |
| Is L_1 finite? | finiteness problem |

Emptiness problem

Theorem (Emptiness problem for regular languages)

The emptiness problem for regular languages is decidable.

Proof.

Algorithm: Let \mathcal{A} be an automaton accepting the language L .

- ▶ Starting with the initial state q_0 , mark all states to which there is a transition from q_0 as **reachable**.
- ▶ Continue with transitions from states which are already marked as **reachable** until either a final state is reached or no further states are reachable.
- ▶ If a final (accepting) state is **reachable**, then $L \neq \{\}$ holds.

Group exercise: Emptiness problem

- ▶ Find an alternative algorithm for the checking emptiness, using the results from the chapter on equivalence.

Word problem

Theorem (Word problem for regular languages)

The word problem for regular languages is decidable.

Proof.

Let $\mathcal{A} = (Q, \Sigma, \delta, q_0, F)$ be a DFA accepting L and $w = c_1c_2 \dots c_n$.

Algorithm:

- ▶ $q_1 := \delta(q_0, c_1)$
- ▶ $q_2 := \delta(q_1, c_2)$
- ▶ \dots
- ▶ If $q_n \in F$ holds, then \mathcal{A} accepts w .

All we have to do is simulate the run of \mathcal{A} on w .

Equivalence problem

Theorem (Equivalence problem for regular languages)

The equivalence problem for regular languages is decidable.

We have already shown how to prove this using minimised DFAs for L_1 and L_2 .

Alternative proof.

One can also use closure properties and decidability of the emptiness problem:

$$L_1 = L_2 \text{ iff } \underbrace{(L_1 \cap \overline{L_2})}_{\text{words that are in } L_1, \text{ but not in } L_2} \cup \underbrace{(\overline{L_1} \cap L_2)}_{\text{words that are not in } L_1, \text{ but in } L_2} = \{\}$$

Finiteness problem

Theorem (Finiteness problem for regular languages)

The finiteness problem for regular languages is decidable.

Proof.

Idea: if there is a loop in an accepting run, words of arbitrary length are accepted.

Let \mathcal{A} be a DFA accepting L .

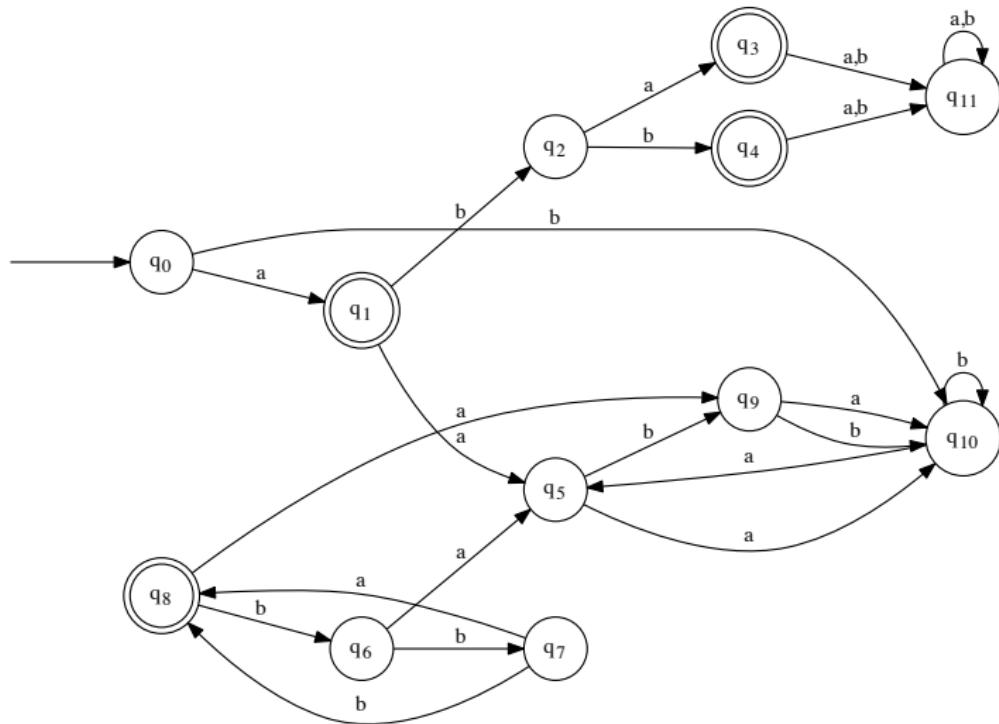

- ▶ Eliminate from \mathcal{A} all states that are not reachable from the initial state, obtaining \mathcal{A}_r .
- ▶ Eliminate from \mathcal{A}_r all states from which no final state is reachable, obtaining \mathcal{A}_f .
- ▶ L is infinite iff \mathcal{A}_f contains a loop.

Note that \mathcal{A}_f may be a NFA (because it misses some transitions)

Exercise: Finiteness

Consider the following DFA \mathcal{A} . Use the previous algorithm to decide if $L(\mathcal{A})$ is finite. Describe $L(\mathcal{A})$.

Regular languages: summary

Regular languages

- ▶ are characterised by
 - ▶ NFAs / DFAs
 - ▶ regular expressions
 - ▶ regular grammars
- ▶ can be transferred from one formalism to another one
- ▶ are **closed** under all operators (considered here)
- ▶ all decision problems (considered here) are **decidable**
- ▶ do not contain several interesting languages ($a^n b^n$, **counting**)
 - ▶ see chapter on **grammars**
- ▶ can express important features of programming languages
 - ▶ keywords
 - ▶ legal identifiers
 - ▶ numbers
- ▶ in compilers, these features are used by **scanners** (next chapter)

End lecture 9

Parsers and Bison

Turing Machines and Languages of Type 1 and 0

Lecture-specific material

Bonus Exercises

Selected Solutions

Computing Environment

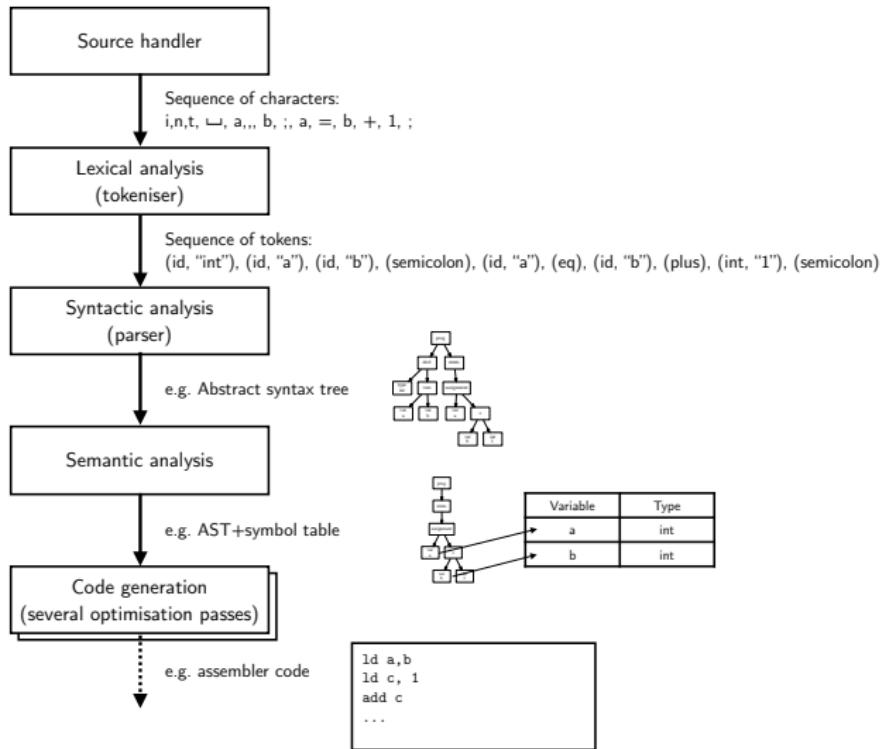

- ▶ For practical exercises, you will need a complete Linux/UNIX environment. If you do not run one natively, there are several options:
 - ▶ You can install VirtualBox (<https://www.virtualbox.org>) and then install e.g. Ubuntu (<http://www.ubuntu.com/>) on a virtual machine. Make sure to install the *Guest Additions*
 - ▶ For Windows, you can install the **complete** UNIX emulation package Cygwin from <http://cygwin.com>
 - ▶ For MacOS, you can install fink (<http://fink.sourceforge.net/>) or MacPorts (<https://www.macports.org/>) and the necessary tools
- ▶ You will need at least flex, bison, gcc, make, and a good text editor

Syntactic Structure of Programming Languages

Most computer languages are mostly context-free

- ▶ Regular: vocabulary
 - ▶ Keywords, operators, identifiers
 - ▶ Described by regular expressions or regular grammar
 - ▶ Handled by (generated or hand-written) scanner/tokenizer/lexer
- ▶ Context-free: program structure
 - ▶ Matching parenthesis, block structure, algebraic expressions, ...
 - ▶ Described by context-free grammar
 - ▶ Handled by (generated or hand-written) parser
- ▶ Context-sensitive: e.g. declarations
 - ▶ Described by human-readable constraints
 - ▶ Handled in an ad-hoc fashion (e.g. symbol table)

High-Level Architecture of a Compiler

Source Handler

- ▶ Handles input files
- ▶ Provides character-by-character access
- ▶ May maintain file/line/column (for error messages)
- ▶ May provide look-ahead

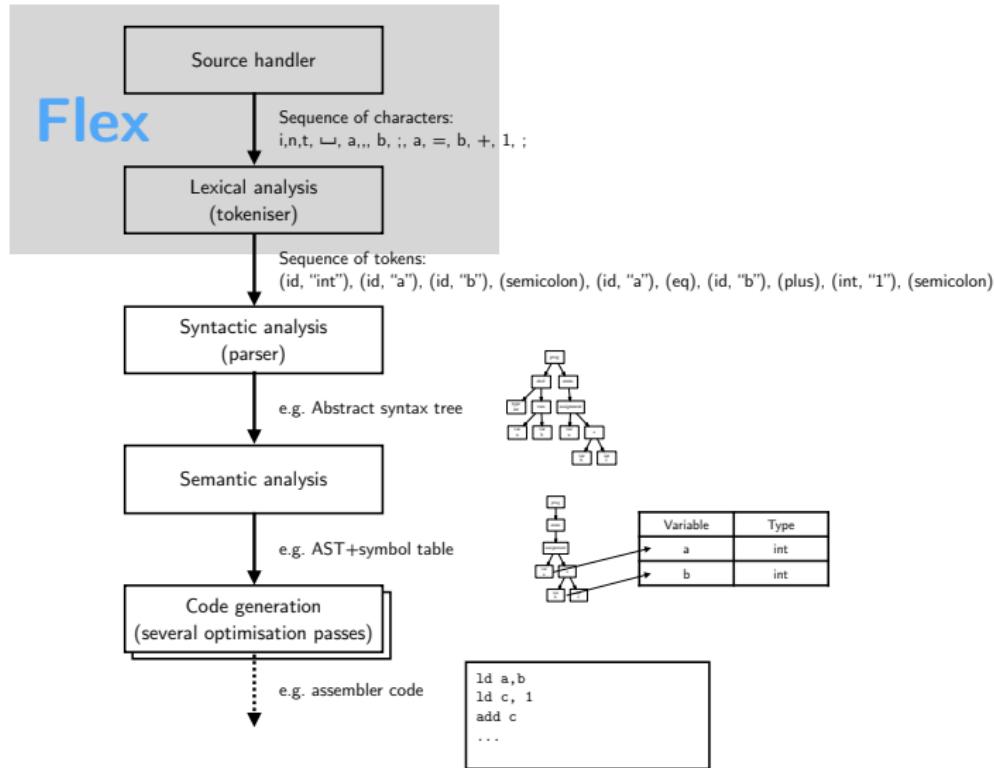

Result: Sequence of characters (with positions)

Lexical Analysis/Scanning

- ▶ Breaks program into **tokens**
- ▶ Typical tokens:
 - ▶ Reserved word (if, while)
 - ▶ Identifier (i, database)
 - ▶ Symbols ({, }, (,), +, -, ...)

Result: Sequence of tokens

Automatisation with Flex

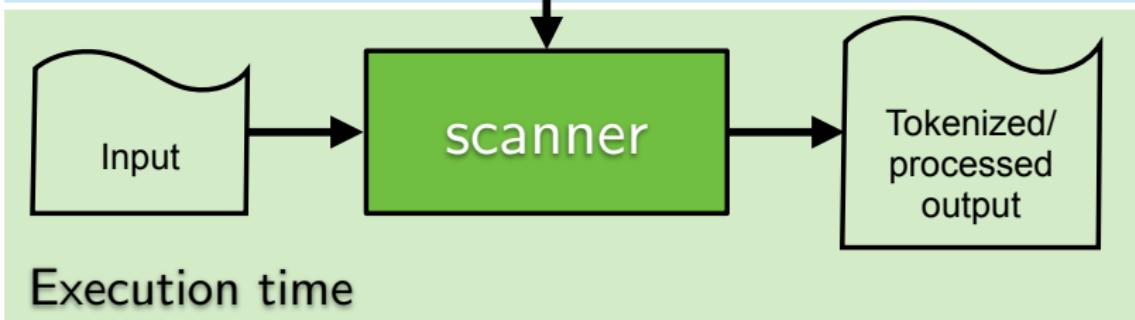

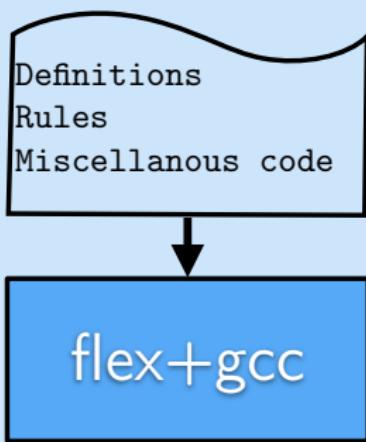

Flex Overview

- ▶ Flex is a **scanner generator**
- ▶ Input: Specification of a regular language and what to do with it
 - ▶ Definitions - named regular expressions
 - ▶ Rules - patterns+actions
 - ▶ (miscellaneous support code)
- ▶ Output: Source code of **scanner**
 - ▶ Scans input for patterns
 - ▶ Executes associated actions
 - ▶ Default action: Copy input to output
 - ▶ Interface for higher-level processing: `yylex()` function

Flex Overview

Development time

Flex Example Task

- ▶ Goal: Sum up all numbers in a file, separately for ints and floats
- ▶ Given: A file with numbers and commands
 - ▶ Ints: Non-empty sequences of digits
 - ▶ Floats: Non-empty sequences of digits, followed by decimal dot, followed by (potentially empty) sequence of digits
 - ▶ Command `print`: Print current sums
 - ▶ Command `reset`: Reset sums to 0.
- ▶ At end of file, print sums

Flex Example Output

Input	Output
12 3.1415	int: 12 ("12")
0.33333	float: 3.141500 ("3.1415")
print reset	float: 0.333330 ("0.33333")
2 11	Current: 12 : 3.474830
1.5 2.5 print	Reset
1	int: 2 ("2")
print 1.0	int: 11 ("11")
	float: 1.500000 ("1.5")
	float: 2.500000 ("2.5")
	Current: 13 : 4.000000
	int: 1 ("1")
	Current: 14 : 4.000000
	float: 1.000000 ("1.0")
	Final 14 : 5.000000

Basic Structure of Flex Files

- ▶ Flex files have 3 sections
 - ▶ Definitions
 - ▶ Rules
 - ▶ User Code
- ▶ Sections are separated by %%
- ▶ Flex files traditionally use the suffix .l

Example Code (definition section)

```
%option noyywrap

DIGIT      [0-9]

%{
    int intval    = 0;
    double floatval = 0.0;
%
%%
```

Example Code (rule section)

```
{DIGIT}+      {
    printf( "int:    %d (\\"%s\\")\n", atoi(yytext), yytext );
    intval += atoi(yytext);
}
{DIGIT}+"."{DIGIT}*        {
    printf( "float: %f (\\"%s\\")\n", atof(yytext),yytext );
    floatval += atof(yytext);
}
reset {
    intval = 0;
    floatval = 0;
    printf("Reset\n");
}
print {
    printf("Current: %d : %f\n", intval, floatval);
}
\n|.{ /* Skip */
}
```

Example Code (user code section)

```
%%
int main( int argc, char **argv )
{
    ++argv, --argc; /* skip over program name */
    if ( argc > 0 )
        yyin = fopen( argv[0], "r" );
    else
        yyin = stdin;

    yylex();

    printf("Final %d : %f\n", intval, floatval);
}
```

Generating a scanner

```
> flex -t numbers.l > numbers.c
> gcc -c -o numbers.o numbers.c
> gcc numbers.o -o scan_numbers
> ./scan_numbers Numbers.txt
int: 12 ("12")
float: 3.141500 ("3.1415")
float: 0.333330 ("0.33333")
Current: 12 : 3.474830
Reset
int: 2 ("2")
int: 11 ("11")
float: 1.500000 ("1.5")
float: 2.500000 ("2.5")
...
...
```

Flexing in detail

```
> flex -tv numbers.l > numbers.c
scanner options: -tvi8 -Cem
37/2000 NFA states
18/1000 DFA states (50 words)
5 rules
Compressed tables always back-up
1/40 start conditions
20 epsilon states, 11 double epsilon states
6/100 character classes needed 31/500 words
of storage, 0 reused
36 state/nextstate pairs created
24/12 unique/duplicate transitions
...
381 total table entries needed
```

Exercise: Building a Scanner

- ▶ Download the `flex` example and input from
[http://wwwlehre.dhbw-stuttgart.de/~sschulz/
fla2017.html](http://wwwlehre.dhbw-stuttgart.de/~sschulz/fla2017.html)
- ▶ Build and execute the program:
 - ▶ Generate the scanner with `flex`
 - ▶ Compile/link the C code with `gcc`
 - ▶ Execute the resulting program in the input file

Definition Section

- ▶ Can contain `flex` options
- ▶ Can contain (C) initialization code
 - ▶ Typically `#include()` directives
 - ▶ Global variable definitions
 - ▶ Macros and type definitions
 - ▶ Initialization code is embedded in `%{` and `%}`
- ▶ Can contain definitions of regular expressions
 - ▶ Format: NAME RE
 - ▶ Defined NAMES can be referenced later

Regular Expressions in Practice (1)

- ▶ The minimal syntax of REs as discussed before suffices to show their equivalence to finite state machines
- ▶ Practical implementations of REs (e.g. in Flex) use a richer and more powerful syntax
- ▶ Regular expressions in Flex are based on the ASCII alphabet
- ▶ We distinguish between the set of operator symbols

$$O = \{ ., *, +, ?, -, ^, |, (,), [], \{, \}, <, >, /, \backslash, ^, \$, " \}$$

and the set of regular expressions

1. $c \in \Sigma_{\text{ASCII}} \setminus O \longrightarrow c \in R$
2. “.” $\in R$
any character but newline (`\n`)

Regular Expressions in Practice (2)

3. $x \in \{a, b, f, n, r, t, v\} \longrightarrow \backslash x \in R$
defines the following control characters
 - \a (alert)
 - \b (backspace)
 - \f (form feed)
 - \n (newline)
 - \r (carriage return)
 - \t (tabulator)
 - \v (vertical tabulator)
4. $a, b, c \in \{0, \dots, 7\} \longrightarrow \backslash abc \in R$ octal representation of a character's ASCII code (e.g. \040 represents the empty space " ")

Regular Expressions in Practice (3)

5. $c \in O \longrightarrow \backslash c \in R$
escaping operator symbols
6. $r_1, r_2 \in R \longrightarrow r_1 r_2 \in R$
concatenation
7. $r_1, r_2 \in R \longrightarrow r_1 | r_2 \in R$
infix operation using “|” rather than “+”
8. $r \in R \longrightarrow r^* \in R$
Kleene star
9. $r \in R \longrightarrow r^+ \in R$
(one or more or r)
10. $r \in R \longrightarrow r? \in R$
optional presence (zero or one r)

Regular Expressions in Practice (4)

11. $r \in R, n \in \mathbb{N} \longrightarrow r\{n\} \in R$
concatenation of n times r
12. $r \in R; m, n \in \mathbb{N}; m \leq n \longrightarrow r\{m, n\} \in R$
concatenation of between m and n times r
13. $r \in R \longrightarrow {}^r \in R$
 r has to be at the **beginning** of line
14. $r \in R \longrightarrow r\$ \in R$
 r has to be at the **end** of line
15. $r_1, r_2 \in R \longrightarrow r_1/r_2 \in R$
The same as r_1r_2 , however, only the contents of r_1 is consumed.
The **trailing context** r_2 can be processed by the next rule.
16. $r \in R \longrightarrow (r) \in R$
Grouping regular expressions with brackets.

Regular Expressions in Practice (5)

17. Ranges

- $[aeiou] \doteq a|e|i|o|u$
- $[a-z] \doteq a|b|c|\dots|z$
- $[a-zA-Z0-9]$: alphanumeric characters
- $[^0-9]$: all ASCII characters w/o digits

18. $[] \in R$

empty space

19. $w \in \{\Sigma_{\text{ASCII}} \setminus \{\backslash, "\}\}^* \longrightarrow "w" \in R$

verbatim text (no escape sequences)

Regular Expressions in Practice (6)

21. $r \in R \longrightarrow \sim r \in R$

The **upto** operator matches the **shortest** string ending with r .

22. predefined character classes

- ▶ [:alnum:] [:alpha:] [:blank:]
- ▶ [:cntrl:] [:digit:] [:graph:]
- ▶ [:lower:] [:print:] [:punct:]
- ▶ [:space:] [:upper:] [:xdigit:]

Regular Expressions in Practice (precedences)

- I. “(”, “)” (strongest)
- II. “*”, “+”, “?”
- III. concatenation
- IV. “|” (weakest)

Example

$$a^*b \mid c^+de \doteq ((a^*)b) \mid (((c^+)d)e)$$

Rule of thumb: *, +, ? bind the smallest possible RE.
Use () if in doubt!

Regular Expressions in Practice (definitions)

- ▶ Assume definition NAME DEF
 - ▶ In later REs. {NAME} is expanded to (DEF)
- ▶ Example:

```
DIGIT      [0-9]  
INTEGER   {DIGIT}+  
PAIR       \({INTEGER}\), {INTEGER}\)
```

Exercise: extended regular expressions

Given the alphabet Σ_{ascii} , how would you express the following practical REs using only the simple REs we have used so far?

- 1 $[a-z]$
- 2 $[^0-9]$
- 3 $(r)^+$
- 4 $(r)\{3\}$
- 5 $(r)\{3,7\}$
- 6 $(r)^\?$

Example Code (definition section) (revisited)

```
%option noyywrap

DIGIT      [0-9]

%{
    int     intval   = 0;
    double floatval = 0.0;
%}

%%
```

Rule Section

- ▶ This is the core of the scanner!
- ▶ Rules have the form `PATTERN ACTION`
- ▶ Patterns are regular expressions
 - ▶ Typically use previous definitions
- ▶ There has to be white space between pattern and action
- ▶ Actions are C code
 - ▶ Can be embedded in `{` and `}`
 - ▶ Can be simple C statements
 - ▶ For a token-by-token scanner, must include `return statement`
 - ▶ Inside the action, the variable `yytext` contains the text matched by the pattern
 - ▶ Otherwise: Full input file is processed

Example Code (rule section) (revisited)

```
{DIGIT}+      {
    printf( "int:    %d (\\"%s\\")\n", atoi(yytext), yytext );
    intval += atoi(yytext);
}
{DIGIT}+"."{DIGIT}*        {
    printf( "float: %f (\\"%s\\")\n", atof(yytext),yytext );
    floatval += atof(yytext);
}
reset {
    intval = 0;
    floatval = 0;
    printf("Reset\n");
}
print {
    printf("Current: %d : %f\n", intval, floatval);
}
\n|.{ /* Skip */
}
```

User code section

- ▶ Can contain all kinds of code
- ▶ For stand-alone scanner: must include `main()`
- ▶ In `main()`, the function `yylex()` will invoke the scanner
- ▶ `yylex()` will read data from the file pointer `yyin`
(so `main()` must set it up reasonably)

Example Code (user code section) (revisited)

```
%%
int main( int argc, char **argv )
{
    ++argv, --argc; /* skip over program name */
    if ( argc > 0 )
        yyin = fopen( argv[0], "r" );
    else
        yyin = stdin;

    yylex();

    printf("Final %d : %f\n", intval, floatval);
}
```

A comment on comments

- ▶ Comments in Flex are complicated
 - ▶ ...because nearly everything can be a pattern
- ▶ Simple rules:
 - ▶ Use old-style C comments /* This is a comment */
 - ▶ Never start them in the first column
 - ▶ Comments are copied into the generated code
 - ▶ Read the manual if you want the dirty details

Flex Miscellaneous

- ▶ Flex online:
 - ▶ <https://github.com/westes/flex>
 - ▶ Manual: <https://westes.github.io/flex/manual/>
 - ▶ REs: <https://westes.github.io/flex/manual/Patterns.html>
- ▶ make knows flex
 - ▶ Make will automatically generate file.o from file.l
 - ▶ Be sure to set LEX=flex to enable flex extensions
 - ▶ Makefile example:

```
LEX=flex
all: scan_numbers
numbers.o: numbers.l

scan_numbers: numbers.o
    gcc numbers.o -o scan_numbers
```

Flexercise (1)

A security audit firm needs a tool that scans documents for the following:

- ▶ Email addresses
 - ▶ Format: String over [A-Za-z0-9_.~-], followed by @, followed by a domain name according to RFC-1034,
<https://tools.ietf.org/html/rfc1034>, Section 3.5 (we only consider the case that the domain name is not empty)
- ▶ (simplified) Web addresses
 - ▶ http:// followed by an RFC-1034 domain name, optionally followed by :<port> (where <port> is a non-empty sequence of digits), optionally followed by one or several parts of the form /<str>, where <str> is a non-empty sequence over [A-Za-z0-9_.~-]

Flexercise (2)

- ▶ Bank account numbers
 - ▶ Old-style bank account numbers start with an identifying string, optionally followed by ., optionally followed by :, optionally followed by spaces, followed by a non-empty sequence of up to 10 digits. Identifying strings are Konto, Kto, KNr, Ktonr, Kontonummer
 - ▶ (German) IBANs are strings starting with DE, followed by exactly 20 digits. Human-readable IBANs have spaces after every 4 characters (the last group has only 2 characters)
- ▶ Examples:
 - ▶ Rosenda@gidwd-39.at.z8o3rw2.zhv
 - ▶ http://jzl.j51g.m-x95.vi5/oj1g_i1/72zz_gt68f
 - ▶ http://iefbottw99.v4gy.zslu9q.zrc2es01nr.dy:8004

Formal Grammars: Motivation

So far, we have seen

- ▶ regular expressions: compact description of regular languages
- ▶ finite automata: **recognise** words of a regular language

Another, more powerful formalism: formal **grammars**

- ▶ **generate** words of a language
- ▶ contain a set of **rules** allowing to replace symbols with different symbols

Grammars: examples

Example (Formal grammars)

$S \rightarrow aA, \quad A \rightarrow bB, \quad B \rightarrow \varepsilon$

generates ab (starting from S): $S \rightarrow aA \rightarrow abB \rightarrow ab$

$S \rightarrow \varepsilon, \quad S \rightarrow aSb$

generates $a^n b^n$

Grammars: definition

Definition (Grammar according to Chomsky)

A (formal) grammar is a quadruple

$$G = (N, \Sigma, P, S)$$

with

- 1 the set of non-terminal symbols N ,
- 2 the set of terminal symbols Σ ,
- 3 the set of production rules P of the form

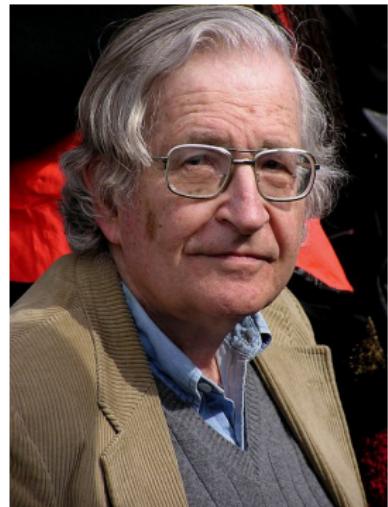

$$\alpha \rightarrow \beta$$

with $\alpha \in V^*NV^*, \beta \in V^*, V = N \cup \Sigma$

- 4 the distinguished start symbol $S \in N$.

Noam Chomsky (*1928)

- ▶ Linguist, philosopher, logician, ...
- ▶ BA, MA, PhD (1955) at the University of Pennsylvania
- ▶ Mainly teaching at MIT (since 1955)
 - ▶ Also Harvard, Columbia University, Institute of Advanced Studies (Princeton), UC Berkely, ...
- ▶ Opposition to Vietnam War, Essay *The Responsibility of Intellectuals*
- ▶ Most cited academic (1980-1992)
- ▶ “World’s top public intellectual” (2005)
- ▶ More than 40 honorary degrees

Grammar for C identifiers

Example (C identifiers)

$G = (N, \Sigma, P, S)$ describes C identifiers:

- ▶ alpha-numeric words
- ▶ which must not start with a digit
- ▶ and may contain an underscore (_)

$N = \{S, R, L, D\}$ (start, rest, letter, digit),

$\Sigma = \{a, \dots, z, A, \dots, Z, 0, \dots, 9, _\}$,

$$\begin{aligned} P = \{ & \quad S \rightarrow LR|_R \\ & \quad R \rightarrow LR|DR|_R|\varepsilon \\ & \quad L \rightarrow a|\dots|z|A|\dots|Z \\ & \quad D \rightarrow 0|\dots|9 \} \end{aligned}$$

$\alpha \rightarrow \beta_1 | \dots | \beta_n$ is an abbreviation for $\alpha \rightarrow \beta_1, \dots, \alpha \rightarrow \beta_n$.

Formal grammars: derivation, language

Definition (Derivation, Language of a Grammar)

For a grammar $G = (N, \Sigma, P, S)$ and words $x, y \in (\Sigma \cup N)^*$, we say that

G derives y from x in one step ($x \Rightarrow_G y$) iff

$$\exists u, v, p, q \in V^* : (x = upv) \wedge (p \rightarrow q \in P) \wedge (y = uqv)$$

Moreover, we say that

G derives y from x ($x \Rightarrow_G^* y$) iff

$$\exists w_0, \dots, w_n$$

with $w_0 = x, w_n = y, w_{i-1} \Rightarrow_G w_i$ for $i \in \{1, \dots, n\}$

The language of G is $L(G) = \{w \in \Sigma^* \mid S \Rightarrow_G^* w\}$

Grammars and derivations

Example (G_3)

Let $G_3 = (N, \Sigma, P, S)$ with

- ▶ $N = \{S\}$,
- ▶ $\Sigma = \{a\}$,
- ▶ $P = \{S \rightarrow aS, \quad S \rightarrow \varepsilon\}$.

Derivations of G_3 have the general form

$$S \Rightarrow aS \Rightarrow aaS \Rightarrow \dots \Rightarrow a^nS \Rightarrow a^n$$

The language produced by G_3 is

$$L(G_3) = \{a^n \mid n \in \mathbb{N}\}.$$

Grammars and derivations (cont')

Example (G_2)

Let $G_2 = (N, \Sigma, P, S)$ with

- ▶ $N = \{S\}$,
- ▶ $\Sigma = \{a, b\}$,
- ▶ $P = \{S \rightarrow aSb, \quad S \rightarrow \varepsilon\}$

Derivations of G_2 :

$$S \Rightarrow aSb \Rightarrow aaSbb \Rightarrow \dots \Rightarrow a^nSb^n \Rightarrow a^n b^n.$$

$$L(G_2) = \{a^n b^n \mid n \in \mathbb{N}\}.$$

Reminder: $L(G_2)$ is not regular!

Grammars and derivations (cont')

Example (G_1)

Let $G_1 = (N, \Sigma, P, S)$ with

- ▶ $N = \{S, B, C\}$,
- ▶ $\Sigma = \{a, b, c\}$,
- ▶ P :

$S \rightarrow aSBC$	1
$S \rightarrow aBC$	2
$CB \rightarrow BC$	3
$aB \rightarrow ab$	4
$bB \rightarrow bb$	5
$bC \rightarrow bc$	6
$cC \rightarrow cc$	7

Exercise: Derivations in G_1

Example (G_1)

Let $G_1 = (N, \Sigma, P, S)$ with

- ▶ $N = \{S, B, C\}$,
- ▶ $\Sigma = \{a, b, c\}$,
- ▶ P :

$S \rightarrow aSBC$	1
$S \rightarrow aBC$	2
$CB \rightarrow BC$	3
$aB \rightarrow ab$	4
$bB \rightarrow bb$	5
$bC \rightarrow bc$	6
$cC \rightarrow cc$	7

- ▶ Give derivations for 3 different words in $L(G_1)$
- ▶ Can you characterize $L(G_1)$?

Grammars and derivations (cont.)

Derivations of G_1 :

$$\begin{aligned} S &\Rightarrow_1 aSBC \Rightarrow_1 aaSBCBC \Rightarrow_1 \dots \Rightarrow_1 a^{n-1}S(BC)^{n-1} \Rightarrow_2 a^n(BC)^n \\ &\Rightarrow_3^* a^nB^nC^n \Rightarrow_{4,5}^* a^n b^n C^n \Rightarrow_{6,7}^* a^n b^n c^n \end{aligned}$$

$$L(G_1) = \{a^n b^n c^n \mid n \in \mathbb{N}; n > 0\}.$$

- ▶ These three derivation examples represent different classes of grammars or languages characterized by different properties.
- ▶ A widely used classification scheme of formal grammars and languages is the [Chomsky hierarchy](#) (1956).

Bonus Exercises

Selected Solutions

The Chomsky hierarchy (0)

Definition (Grammar of type 0)

Every Chomsky grammar $G = (N, \Sigma, P, S)$ is of Type 0 or unrestricted.

The Chomsky hierarchy (1)

Definition (context-sensitive grammar)

A Chomsky grammar $G = (N, \Sigma, P, S)$ is of is **Type 1** (**context-sensitive**) if all productions are of the form

$$\alpha \rightarrow \beta \quad \text{with} \quad |\alpha| \leq |\beta|$$

Exception: the rule $S \rightarrow \varepsilon$ is allowed if S does not appear on the right-hand side of any rule

- ▶ Rules never derive shorter words
 - ▶ except for the empty word in the first step

Context-sensitive vs. monotonic grammars

- ▶ Grammars of the type defined on the last slide were originally called **monotonic** or **non-contracting** by Chomsky
- ▶ Context-sensitive grammars additionally have to satisfy:

$$\alpha_1 A \alpha_2 \rightarrow \alpha_1 \beta \alpha_2 \text{ with } A \in N; \alpha_1, \alpha_2 \in V^*, \beta \in VV^*$$

- ▶ rule application can depend on a context α_1, α_2
- ▶ context cannot be modified (or moved)
- ▶ only **one NTS** can be modified
- ▶ every monotonic grammar can be rewritten as context-sensitive
 - ▶ $AB \rightarrow BA$ is not context-sensitive, but $AB \rightarrow AY \rightarrow XY \rightarrow XA \rightarrow BA$
 - ▶ if terminal symbols are involved: replace $S \rightarrow aB \rightarrow ba$ with
 $S \rightarrow N_a B \rightarrow \dots N_b N_a \rightarrow bN_a \rightarrow ba$
- ▶ since context is irrelevant for the language class, we drop the context requirement for this lecture
- ▶ since the term “context-sensitive” is generally used in the literature, we stick with this term (for both grammars and languages)

The Chomsky hierarchy (2)

Definition (context-free grammar)

A Chomsky grammar $G = (N, \Sigma, P, S)$ is of is **Type 2 (context-free)** if all productions are of the form

$$A \rightarrow \beta \text{ with } A \in N; \beta \in V^*$$

- ▶ Only single non-terminals are replaced
 - ▶ independent of their context
- ▶ Contracting rules are **allowed!**
 - ▶ context-free grammars are **not** a subset of context-sensitive grammars
 - ▶ but: context-free **languages** are a subset of context-sensitive **languages**
 - ▶ reason: contracting rules can be removed from context-free grammars, but not from context-sensitive ones

The Chomsky hierarchy (3)

Definition (right-linear grammar)

A Chomsky grammar $G = (N, \Sigma, P, S)$ is of **Type 3 (right-linear or regular)** if all productions are of the form

$$A \rightarrow aB$$

with $A \in N; B \in N \cup \{\varepsilon\}; a \in \Sigma \cup \{\varepsilon\}$

- ▶ only one NTS on the left
- ▶ on the right: one TS, one NTS, both, or neither
- ▶ analogy with automata is obvious

Formal grammars and formal languages

Definition (language classes)

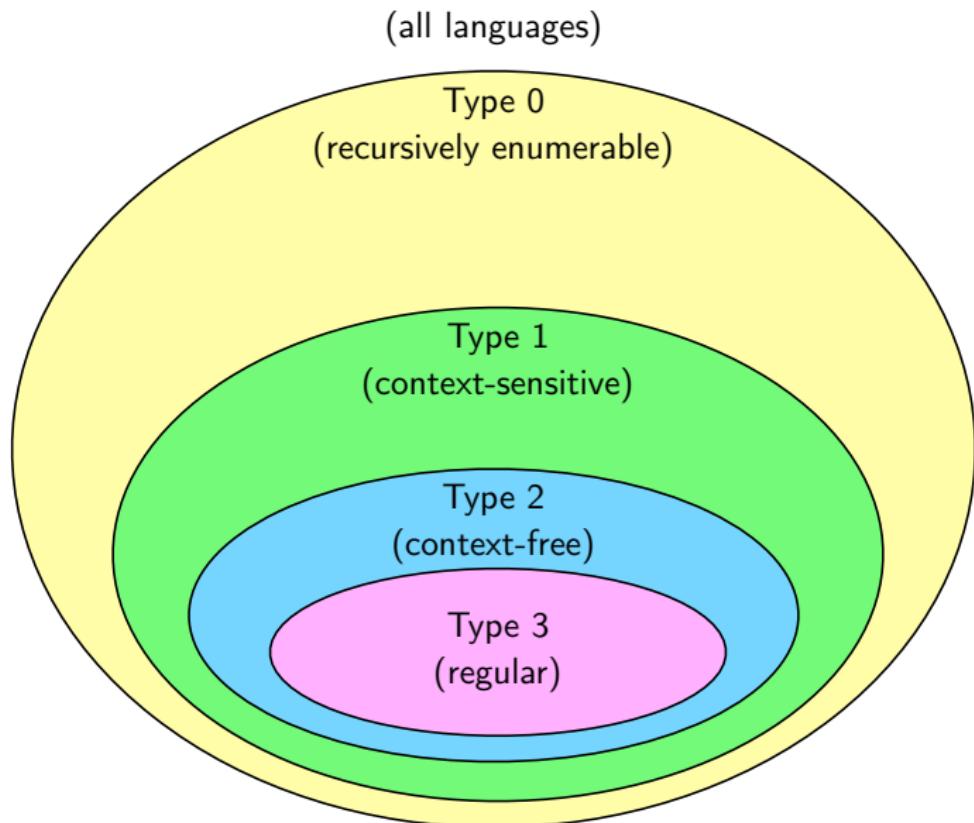

A language is called
recursively enumerable, context-sensitive, context-free, or regular,
if it can be generated by a
unrestricted, context-sensitive, context-free, or regular
grammar, respectively.

Formal grammars vs. formal languages vs. machines

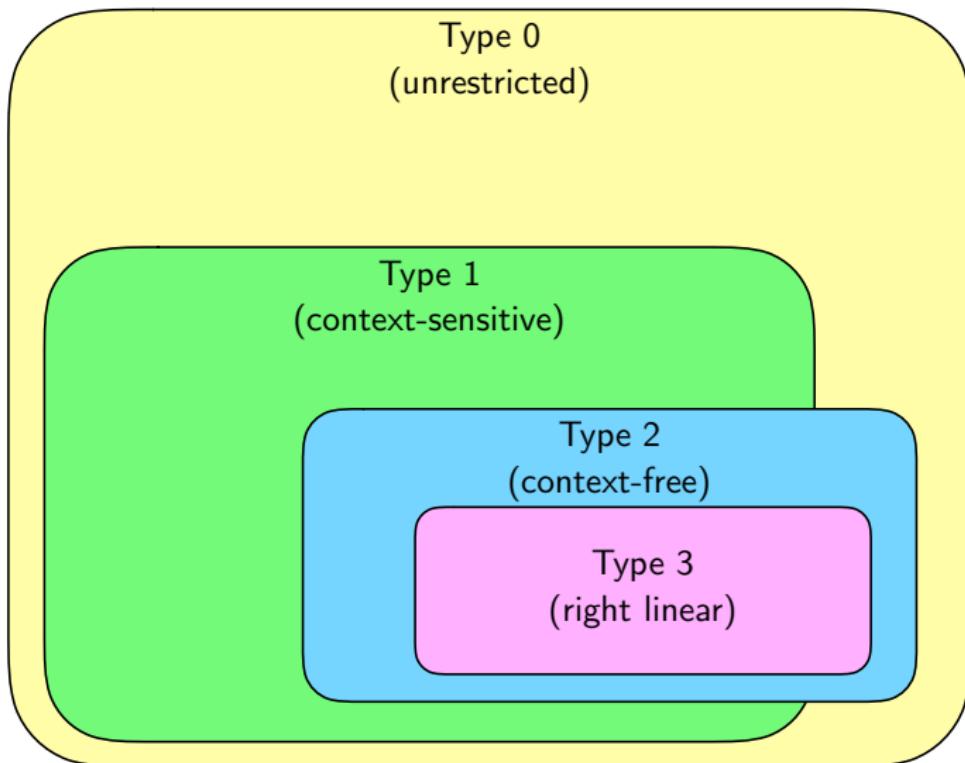

For each grammar/language type, there is a corresponding type of machine model:

grammar	language	machine
Type 0 unrestricted	recursively enumerable	Turing machine
Type 1	context-sensitive	linear-bounded non-deterministic Turing machine
Type 2	context-free	non-deterministic pushdown automaton
Type 3 right linear	regular	finite automaton

The Chomsky Hierarchy for Languages

The Chomsky Hierarchy for Grammars

The Chomsky hierarchy: examples

Example (∞ identifiers revisited)

$$S \rightarrow LR|_R$$

$$R \rightarrow LR|DR|_R|\varepsilon$$

$$L \rightarrow a| \dots |z|A| \dots |z$$

$$D \rightarrow 0| \dots |9$$

This grammar is context-free but not regular.

An equivalent regular grammar:

$$S \rightarrow AR| \dots |zR|aR| \dots |zR|_R$$

$$R \rightarrow AR| \dots |zR|aR| \dots |zR|0R| \dots |9R|_R|\varepsilon$$

The Chomsky hierarchy: examples revisited

Returning to the three derivation examples:

- ▶ G_3 with $P = \{S \rightarrow aS, S \rightarrow \varepsilon\}$
 - ▶ G_3 is regular.
 - ▶ So is the produced language $L_3 = \{a^n \mid n \in \mathbb{N}\}$.
- ▶ G_2 with $P = \{S \rightarrow aSb, S \rightarrow \varepsilon\}$
 - ▶ G_2 is context-free.
 - ▶ So is the produced language $L_2 = \{a^n b^n \mid n \in \mathbb{N}\}$.
- ▶ G_1 with $P = \{S \rightarrow aSBC, S \rightarrow aBC, CB \rightarrow BC, \dots\}$
 - ▶ G_1 is context-sensitive.
 - ▶ So is the produced language $L_1 = \{a^n b^n c^n \mid n \in \mathbb{N}; n > 0\}$.

The Chomsky hierarchy: exercises

1 Let $G = (N, \Sigma, P, S)$ with

- ▶ $N = \{S, A, B\}$,
- ▶ $\Sigma = \{a\}$,
- ▶ $P :$

$S \rightarrow \varepsilon$	1
$S \rightarrow ABA$	2
$AB \rightarrow aa$	3
$aA \rightarrow aaaA$	4
$A \rightarrow a$	5

- a) What is G 's highest type?
- b) Show how G derives the word $aaaaaa$.
- c) Formally describe the language $L(G)$.
- d) Define a regular grammar G' equivalent to G .

The Chomsky hierarchy: exercises (cont.)

- 2 An **octal constant** is a finite sequence of digits starting with 0 followed by at least one digit ranging from 0 to 7. Define a regular grammar encoding exactly the set of possible octal constants.

The Chomsky hierarchy: exercises (cont.)

3 Let $G = (N, \Sigma, P, S)$ with

- ▶ $N = \{S, A, B\}$,
- ▶ $\Sigma = \{a, b, t\}$,
- ▶ $P : \begin{array}{ll} S \rightarrow aAS & 1 \\ S \rightarrow bBS & 2 \\ S \rightarrow t & 3 \\ At \rightarrow ta & 4 \\ Bt \rightarrow tb & 5 \end{array}$

- | | |
|---------------------|---|
| $Aa \rightarrow aA$ | 6 |
| $Ab \rightarrow bA$ | 7 |
| $Ba \rightarrow aB$ | 8 |
| $Bb \rightarrow bB$ | 9 |

- What is G 's highest type?
- Formally describe the language $L(G)$.

Right-linear grammars and regular languages

Regular languages and right-linear grammars

Theorem (right-linear grammars and regular languages)

The class of regular languages (generated by regular expressions, accepted by finite automata) is exactly the class of languages generated by right-linear grammars.

Proof.

- ▶ Convert DFA to right-linear grammar
- ▶ Convert right-linear grammar to NFA

DFA \leadsto right-linear grammar

Algorithm for transforming a DFA

$$\mathcal{A} = (Q, \Sigma, \delta, q_0, F)$$

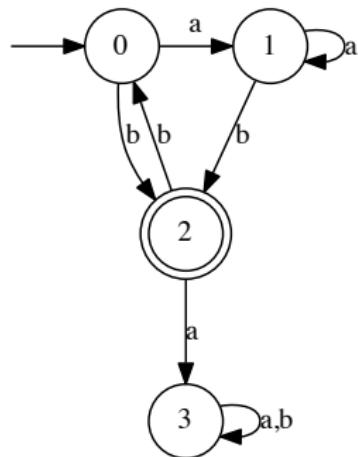

into a grammar

$$G = (N, \Sigma, P, S)$$

- ▶ $N = Q$
- ▶ $S = q_0$
- ▶ $P = \{p \rightarrow aq \mid ((p, a), q) \in \delta\} \quad \cup \quad \{p \rightarrow \varepsilon \mid p \in F\}$

Exercise: DFA to right-linear grammar

Consider the following DFA \mathcal{A} :

- Give a formal definition of \mathcal{A}
- Generate a right-linear grammar G with $L(G) = L(\mathcal{A})$

Right-linear grammar \rightsquigarrow NFA

Algorithm for transforming a grammar

$$G = (N, \Sigma, P, S)$$

into an NFA

$$\mathcal{A} = (Q, \Sigma, \Delta, q_0, F)$$

- ▶ $Q = N \cup \{q_f\}$ ($q_f \notin N$)
- ▶ $q_0 = S$
- ▶ $F = \{q_f\}$
- ▶ $\Delta = \{(A, c, B) \mid A \rightarrow cB \in P\} \cup$
 $\{(A, c, q_f) \mid A \rightarrow c \in P\} \cup$
 $\{(A, \varepsilon, B) \mid A \rightarrow B \in P\} \cup$
 $\{(A, \varepsilon, q_f) \mid A \rightarrow \varepsilon \in P\}$

Exercise: right-linear grammar to NFA

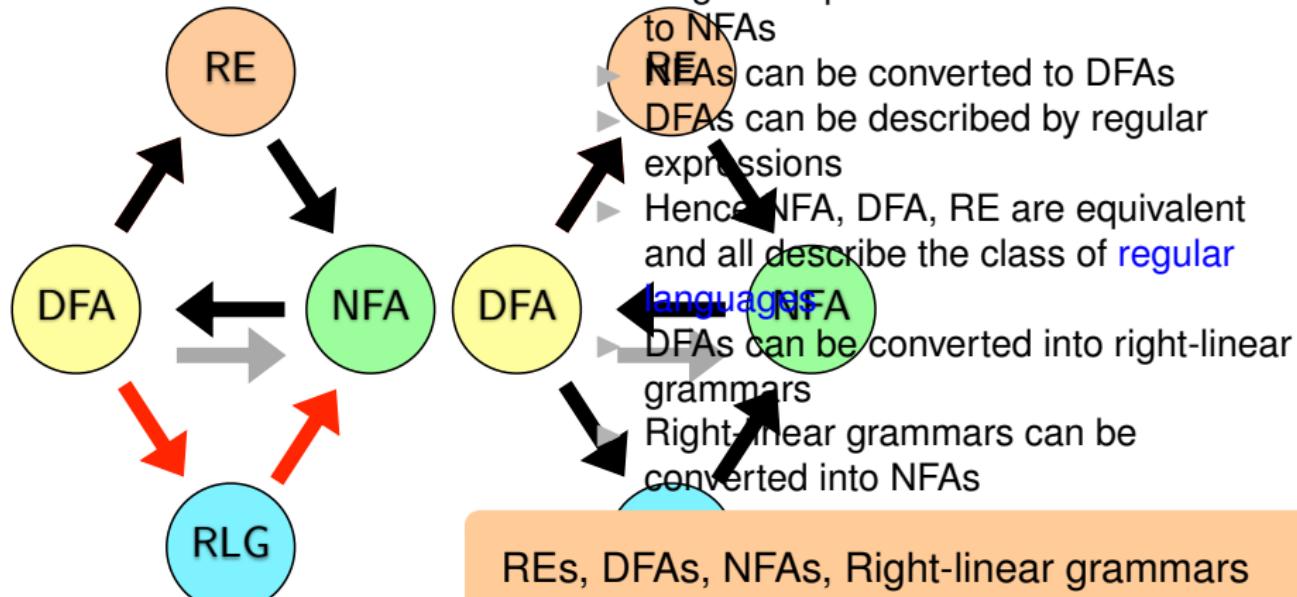

Transform the grammar $G = (\{S, A, B\}, \{a, b\}, P, S)$ into an NFA.

$$\begin{array}{lll} P : & S & \rightarrow aB|\varepsilon \\ & A & \rightarrow aB|b \\ & B & \rightarrow A \end{array}$$

Which language is generated by G ?

Right-linear grammars and regular languages

► We now know:

REs, DFAs, NFAs, Right-linear grammars are all equivalent formalisms do describe the class of regular languages!

Lecture-specific material

Bonus Exercises

Selected Solutions

Context-free grammars

- ▶ Reminder: $G = (N, \Sigma, P, S)$ is context-free if all rules in P are of the form $A \rightarrow \beta$ with
 - ▶ $A \in N$ and
 - ▶ $\beta \in (\Sigma \cup N)^*$
- ▶ Context-free languages/grammars are highly relevant for practical applications
 - ▶ Core of most programming languages
 - ▶ XML
 - ▶ Algebraic expressions
 - ▶ Many aspects of human language

Grammars: equivalence and normal forms

Definition (equivalence)

Two grammars are called **equivalent** if they generate the same language.

We will now compute grammars that are equivalent to some given context-free grammar G but have “nicer” properties

- ▶ **Reduced** grammars contain no unproductive symbols
- ▶ Grammars in **Chomsky normal form** support efficient decision of the **word problem**

I.e. grammars in CNF allow efficient parsing of arbitrary context-free languages!

Reduced grammars

Definition (reduced)

Let $G = (N, \Sigma, P, S)$ be a context-free grammar.

- ▶ $A \in N$ is called **terminating** if $A \Rightarrow_G^* w$ for some $w \in \Sigma^*$.
- ▶ $A \in N$ is called **reachable** if $S \Rightarrow_G^* uAv$ for some $u, v \in V^*$.
- ▶ G is called **reduced** if N contains only reachable and terminating symbols.

Terminating and reachable symbols

The terminating symbols can be computed as follows:

- 1 $T := \{A \in N \mid \exists w \in \Sigma^* : A \rightarrow w \in P\}$
- 2 add all symbols M to T with a rule $M \rightarrow D$ with $D \in (\Sigma \cup T)^*$
- 3 repeat step 2 until no further symbols can be added

Now T contains exactly the terminating symbols.

The reachable symbols can be computed as follows:

- 1 $R := \{S\}$
- 2 for every $A \in R$, add all symbols M with a rule $A \rightarrow V^* M V^*$
- 3 repeat step 2 until no further symbols can be added

Now R contains exactly the reachable symbols.

Reducing context-free grammars

Theorem (reduction of context-free grammars)

Every context-free grammar G can be transformed into an equivalent reduced context-free grammar G_r .

Proof.

- 1 generate the grammar G_T by removing all **non-terminating symbols** (and rules containing them) from G
- 2 generate the grammar G_r by removing all **unreachable symbols** (and rules containing them) from G_T

Sequence is important: symbols can become unreachable through removal of non-terminating symbols.

Reachable and terminating symbols

Example

Let $G = (N, \Sigma, P, S)$ with

- ▶ $N = \{S, A, B, C, T\}$,

- ▶ $\Sigma = \{a, b, c\}$,

- ▶ $P :$

$$S \rightarrow T|B|C$$

$$T \rightarrow AB$$

$$A \rightarrow a$$

$$B \rightarrow bB$$

$$C \rightarrow c$$

- ▶ terminating symbols in G : $C, A, S \rightsquigarrow G_T$
- ▶ reachable symbols in G_T : $S, C \rightsquigarrow G_r$
- ▶ note: A is still reachable in G !

Exercise: reducing grammars

Compute the reduced grammar $G = (N, \Sigma, P, S)$ for the following grammar $G' = (N', \Sigma, P', S)$:

1 $N' = \{S, A, B, C, D\}$,

2 $\Sigma = \{a, b\}$,

3 P' :

$$S \rightarrow A|aS|B$$

$$A \rightarrow a$$

$$A \rightarrow AS$$

$$A \rightarrow Ba$$

$$B \rightarrow Ba$$

$$C \rightarrow Da$$

$$D \rightarrow Cb$$

$$D \rightarrow a$$

Chomsky normal form

Reduced grammars can be further modified to allow for an efficient decision procedure for the word problem.

Definition (CNF)

A context-free grammar (N, Σ, P, S) is in **Chomsky normal form** if all rules are of the kind

- ▶ $N \rightarrow a$ with $a \in \Sigma$
- ▶ $N \rightarrow AB$ with $A, B \in N$
- ▶ $S \rightarrow \varepsilon$, if S does not appear on the right-hand side of any rule

Transformation of a reduced grammar into CNF:

- 1 remove ε -productions
- 2 remove chain rules ($A \rightarrow B$)
- 3 introduce auxiliary symbols

Removal of ε -productions

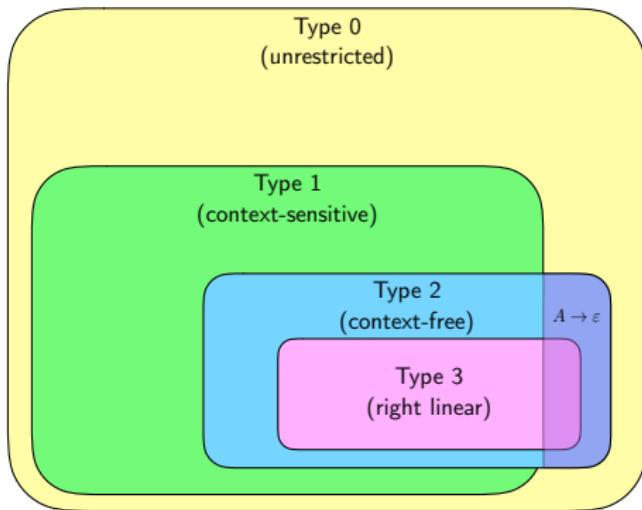

Theorem (ε -free grammar)

Every context-free grammar can be transformed into an equivalent cf. grammar that does not contain rules of the kind $A \rightarrow \varepsilon$ (except $S \rightarrow \varepsilon$ if S does not appear on the rhs).

Procedure:

- 1 let $E = \{A \in N \mid A \rightarrow \varepsilon \in P\}$
- 2 add all symbols B to E for which there is a rule $B \rightarrow \beta$ with $\beta \in E^*$
- 3 repeat step 2 until no further symbols can be added
- 4 for every rule $C \rightarrow \beta_1 B \beta_2$ with $B \in E$
 - ▶ add rule $C \rightarrow \beta_1 \beta_2$ to P
 - ▶ repeat this process until no new rules are added
- 5 remove all rules $A \rightarrow \varepsilon$ from P
- 6 if $S \in E$
 - ▶ use a new start symbol S_0
 - ▶ add rules $S_0 \rightarrow \varepsilon | S$

Interlude: Chomsky-Hierarchy for Grammars (again)

- ▶ For languages, Type-0, Type-1, Type-2, Type-3 form a real inclusion hierarchy
- ▶ Not quite true for grammars:
 - ▶ $A \rightarrow \varepsilon$ allowed in context-free/regular grammars, not in context-sensitive grammars
 - ▶ Eliminating ε -productions removes this discrepancy!

End lecture 12

Removal of chain rules

Theorem (chain rules)

Every context-free grammar can be transformed into an equivalent cf. grammar that does not contain rules of the kind $A \rightarrow B$.

Procedure:

- 1 for every $A \in N$, compute the set $N(A) = \{B \in N \mid A \Rightarrow_G^* B\}$
(this can be done iteratively, as shown previously)
- 2 remove $A \rightarrow C$ for any $C \in N$ from P
- 3 add the following production rules to P
 $\{A \rightarrow w \mid w \notin N \text{ and } B \rightarrow w \in P \text{ and } B \in N(A)\}$

Example

$$A \rightarrow a|B; \quad B \rightarrow bb|C; \quad C \rightarrow ccc$$

is equivalent to

$$A \rightarrow a|bb|ccc; B \rightarrow bb|ccc; C \rightarrow ccc$$

Chomsky normal form

Reminder: Chomsky normal form

A context-free grammar (N, Σ, P, S) is in CNF if all rules are of the kind

- ▶ $N \rightarrow a$ with $a \in \Sigma$
- ▶ $N \rightarrow AB$ with $A, B \in N$
- ▶ $S \rightarrow \varepsilon$, if S does not appear on the right-hand side of any rule

Theorem (transformation into Chomsky normal form)

Every context free grammar can be transformed into an equivalent cf. grammar in Chomsky normal form.

Algorithm for computing Chomsky normal form

- 1 remove ε rules
- 2 remove chain rules
- 3 compute reduced grammar
 - 1 remove non-terminating symbols
 - 2 remove unreachable symbols
- 4 for all rules $A \rightarrow w$ with $w \notin \Sigma$:
 - replace all occurrences of a with X_a for all $a \in \Sigma$
 - add rules $X_a \rightarrow a$
- 5 replace rules $A \rightarrow B_1B_2 \dots B_n$ for $n > 2$ with rules

$$\begin{aligned} A &\rightarrow B_1 C_1 \\ C_1 &\rightarrow B_2 C_2 \\ &\vdots \\ C_{n-2} &\rightarrow B_{n-1} B_n \end{aligned}$$

with new symbols C_i .

Exercise: transformation into CNF

Compute the Chomsky normal form of the following grammar:

$$G = (N, \Sigma, P, S)$$

- ▶ $N = \{S, A, B, C, D, E\}$
- ▶ $\Sigma = \{a, b\}$
- ▶ $P :$

$$S \rightarrow AB|SB|BDE$$

$$A \rightarrow Aa$$

$$B \rightarrow bB|BaB|ab$$

$$C \rightarrow SB$$

$$D \rightarrow E$$

$$E \rightarrow \varepsilon$$

Solution

Chomsky NF: purpose

Why transform G into Chomsky NF?

- ▶ in a context-free grammar, derivations can have arbitrary length
 - ▶ if there are contracting rules, a derivation of w can contain words longer than w
 - ▶ if there are chain rules ($C \rightarrow B; B \rightarrow C$), a derivation of w can contain arbitrarily many steps
- ▶ word problem is difficult to decide
- ▶ if G is in CNF, for a word of length n , a derivation has $2n - 1$ steps:
 - ▶ $n - 1$ rule applications $A \rightarrow BC$
 - ▶ n rule applications $A \rightarrow a$
- ▶ word problem can be decided by checking all derivations of length $2n - 1$
- ▶ That's still plenty of derivations!

More efficient algorithm: Cocke-Younger-Kasami (CYK)

CYK algorithm: idea

Decide the word problem for a context-free grammar G in Chomsky NF and a word w .

- ▶ find out which NTS are needed in the end to produce the TS for w (using production rules $A \rightarrow a$).
- ▶ iteratively find all NTS that can generate the required sequence of NTS (using production rules $A \rightarrow BC$).
- ▶ if S can produce the required sequence, $w \in L(G)$ holds.

Mechanism:

- ▶ operates on a table.
- ▶ field in row i and column j contains all NTS that can generate words from character i through j .

Example of dynamic programming!

CYK algorithm: example

$$S \rightarrow a$$

$$B \rightarrow b$$

$$B \rightarrow c$$

$$S \rightarrow SA$$

$$A \rightarrow BS$$

$$B \rightarrow BB$$

$$B \rightarrow BS$$

$i \setminus j$	1	2	3	4	5	6
1	S	$\{\}$	S	$\{\}$	$\{\}$	S
2		B	A, B	B	B	A, B
3			S	$\{\}$	$\{\}$	S
4				B	B	A, B
5					B	A, B
6						S

$w =$	a	b	a	c	b	a
-------	---	---	---	---	---	---

$$w = abacba$$

CYK: formal algorithm

for $i := 1$ to n **do**

$$N_{ii} := \{A \mid A \rightarrow a_i \in P\}$$

for $d := 1$ to $n - 1$ **do**

for $i := 1$ to $n - d$ **do**

$$j := i + d$$

$$N_{ij} := \{\}$$

for $k := i$ to $j - 1$ **do**

$$N_{ij} := N_{ij} \cup \{A \mid A \rightarrow BC \in P; B \in N_{ik}; C \in N_{(k+1)j}\}$$

CYK algorithm: exercise

Consider the grammar

$G = (N, \Sigma, P, S)$ from the previous
exercise

- ▶ $N = \{S, A, B, D, X, Y\}$
- ▶ $\Sigma = \{a, b\}$

$$\begin{array}{lll} P : & S & \rightarrow SB|BD|YB|XY \\ & B & \rightarrow BD|YB|XY \\ & D & \rightarrow XB \\ & X & \rightarrow a \\ & Y & \rightarrow b \end{array}$$

Use the CYK algorithm to determine if the following words can be generated by G :

- a) $w_1 = babaab$
- b) $w_2 = abba$

End lecture 13

Bonus Exercises

Selected Solutions

Pushdown automata: motivation

- ▶ DFAs/NFAs are weaker than context-free grammars
- ▶ to accept languages like $a^n b^n$, an **unlimited storage component** is needed
- ▶ **Pushdown automata** have an unlimited **stack**
 - ▶ LIFO: last in, first out
 - ▶ only top symbol can be read
 - ▶ arbitrary amount of symbols can be added to the top

PDA: conceptual model

- ▶ extends FA by **unlimited stack**:
 - ▶ transitions can read and **write** stack
 - ▶ only at the top
 - ▶ **stack alphabet** Γ
 - ▶ **LIFO**: last in, first out
- ▶ acceptance condition
 - ▶ **empty stack** after reading input
 - ▶ no final states needed
- ▶ commonalities with FA:
 - ▶ read input from left to right
 - ▶ set of states, input alphabet
 - ▶ initial state

PDA transitions

$$\Delta \subseteq Q \times \Sigma \cup \{\varepsilon\} \times \Gamma \times \Gamma^* \times Q$$

- ▶ PDA is in a state
- ▶ can read next input character or nothing
- ▶ must read (and remove) top stack symbol
- ▶ can write arbitrary amount of symbols on top of stack
- ▶ goes into a new state

A transition (p, c, A, BC, q) can be written as follows:

$$p \quad c \quad A \quad \rightarrow \quad BC \quad q$$

Pushdown automata: definition

Definition (pushdown automaton)

A **pushdown automaton** (PDA) is a 6-tuple $(Q, \Sigma, \Gamma, \Delta, q_0, Z_0)$ where

- ▶ Q, Σ, q_0 are defined as for NFAs.
- ▶ Γ is the stack alphabet
- ▶ Z_0 is the initial stack symbol
- ▶ $\Delta \subseteq Q \times \Sigma \cup \{\varepsilon\} \times \Gamma \times \Gamma^* \times Q$ is the transition relation

A **configuration** of a PDA is a triple (q, w, γ) where

- ▶ q is the current state
- ▶ w is the input yet unread
- ▶ γ is the current stack content

A PDA \mathcal{A} **accepts** a word $w \in \Sigma^*$ if, starting from the configuration (q_0, w, Z_0) , \mathcal{A} can reach the configuration $(q, \varepsilon, \varepsilon)$ for some q .

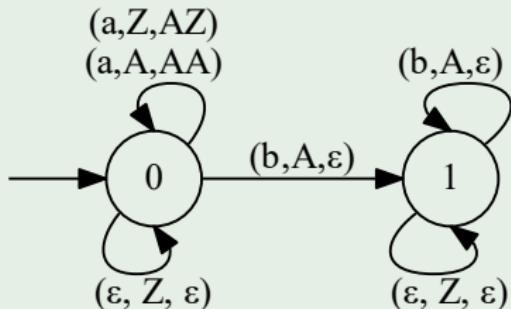

Example: PDA for $a^n b^n$

Example (Automaton \mathcal{A})

$$\mathcal{A} = (Q, \Sigma, \Gamma, \Delta, 0, Z)$$

- ▶ $Q = \{0, 1\}$
- ▶ $\Sigma = \{a, b\}$
- ▶ $\Gamma = \{A, Z\}$
- ▶ $\Delta :$

0	ε	Z	\rightarrow	ε	0	accept empty word
0	a	Z	\rightarrow	AZ	0	read first a, store A
0	a	A	\rightarrow	AA	0	read further a, store A
0	b	A	\rightarrow	ε	1	read first b, delete A
1	b	A	\rightarrow	ε	1	read further b, delete A
1	ε	Z	\rightarrow	ε	1	accept if all As have been deleted

PDA: example (2)

Process $aabb$:

- 1 (0, $aabb$, Z)
- 2 (0, abb , AZ)
- 3 (0, bb , AAZ)
- 4 (1, b , AZ)
- 5 (1, ε , Z)
- 6 (1, ε , ε)

0	ε	Z	\rightarrow	ε	0
0	a	Z	\rightarrow	AZ	0
0	a	A	\rightarrow	AA	0
0	b	A	\rightarrow	ε	1
1	b	A	\rightarrow	ε	1
1	ε	Z	\rightarrow	ε	1

Process abb :

- 1 (0, abb , Z)
- 2 (0, bb , AZ)
- 3 (1, b , Z)
- 4 (1, b , ε)
- 5 No rule applicable,
input not read entirely

PDAs: important properties

- ▶ Γ and Σ do not need to be disjoint
 - ▶ Not uncommon: $\Sigma \subseteq \Gamma$
 - ▶ ... but convention: Σ lowercase letters, Γ uppercase letters
- ▶ ε transitions are possible
 - ▶ ... and can modify the stack
- ▶ PDAs as defined above are **non-deterministic**
 - ▶ Deterministic PDA: For each situation there is only one applicable transition (either ε or c)
 - ▶ deterministic PDAs are strictly weaker
- ▶ We can also define PDAs with acceptance via final states, but...
 - ▶ this makes representation of PDAs more complex
 - ▶ makes proofs more difficult

PDA: exercise

Define a PDA detecting all palindromes over $\Sigma = \{a, b\}$, i.e. all words

$$\{w \cdot \overleftarrow{w} \mid w \in \Sigma^*\}$$

where

$$\overleftarrow{w} = a_n \dots a_1 \text{ if } w = a_1 \dots a_n$$

Can you define a deterministic automaton?

Equivalence of PDAs and Context-Free Grammars

Theorem

The class of languages that can be accepted by a PDA is exactly the class of languages that can be produced by a context-free grammar.

Proof.

- ▶ For a cf. grammar G , generate a PDA \mathcal{A}_G with $L(\mathcal{A}_G) = L(G)$.
- ▶ For a PDA \mathcal{A} , generate a cf. grammar $G_{\mathcal{A}}$ with $L(G_{\mathcal{A}}) = L(\mathcal{A})$.

From context-free grammars to PDAs

For a grammar $G = (N, \Sigma, P, S)$, an equivalent PDA is:

$$\mathcal{A}_G = (\{q\}, \Sigma, \Sigma \cup N, \Delta, q, S)$$

$$\begin{aligned}\Delta = & \{(q, \varepsilon, A, \gamma, q) \mid A \rightarrow \gamma \in P\} \quad \cup \\ & \{(q, a, a, \varepsilon, q) \mid a \in \Sigma\}\end{aligned}$$

\mathcal{A}_G simulates the productions of G in the following way:

- ▶ a production rule is applied to the top stack symbol if it is an NTS
- ▶ a TS is removed from the stack if it corresponds to the next input character

Note:

- ▶ \mathcal{A}_G is nondeterministic if there are several rules for one NTS.
- ▶ \mathcal{A}_G only has one single state.
 - ▶ Corollary: PDAs need no states, could be written as $(\Sigma, \Gamma, \Delta, Z_0)$.

From context-free grammars to PDAs: exercise

For the grammar $G = (\{S\}, \{a, b\}, P, S)$ with

$$\begin{aligned}P = \{ & S \rightarrow aSa \\& S \rightarrow bSb \\& S \rightarrow \varepsilon \}\end{aligned}$$

- ▶ create an equivalent PDA \mathcal{A}_G ,
- ▶ show how \mathcal{A}_G processes the input $abba$.

From PDAs to context-free grammars

Transforming a PDA $\mathcal{A} = (Q, \Sigma, \Gamma, \Delta, q_0, Z_0)$ into a grammar $G_{\mathcal{A}} = (N, \Sigma, P, S)$ is more involved:

- ▶ N contains symbols $[pZq]$, meaning
 - ▶ \mathcal{A} must go from p to q deleting Z from the stack
- ▶ for a transition $(p, a, Z, \varepsilon, q)$ that deletes a stack symbol:
 - ▶ \mathcal{A} can switch from p to q and delete Z by reading input a
 - ▶ this can be expressed by a production rule $[pZq] \rightarrow a$.
- ▶ for transitions (p, a, Z, ABC, q) that produce stack symbols:
 - ▶ test all possible transitions for removing these symbols
 - ▶ $[pZt] \rightarrow a[qAr][rBs][sCt]$ for all states r, s, t
 - ▶ intuitive meaning: in order to go from p to t and delete Z , you can
 - 1 read the input a
 - 2 go into state q
 - 3 find states r, s through which you can go from q to t and delete A, B , and C from the stack.

$G_{\mathcal{A}}$: formal definition

For $\mathcal{A} = (Q, \Sigma, \Gamma, \Delta, q_0, Z_0)$ we define $G_{\mathcal{A}} = (N, \Sigma, P, S)$ as follows

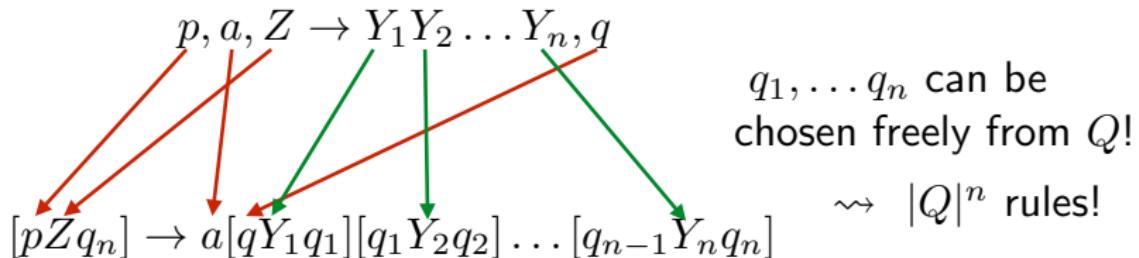

- ▶ $N = \{S\} \cup \{[pZq] \mid p, q \in Q, Z \in \Gamma\}$
- ▶ P contains the following rules:
 - ▶ for every $q \in Q$, P contains $\{S \rightarrow [q_0Z_0q]\}$
meaning: \mathcal{A} has to go from q_0 to any state q , deleting Z_0 .
 - ▶ for each transition $(p, a, Z, Y_1Y_2 \dots Y_n, q)$ with
 - ▶ $a \in \Sigma \cup \{\varepsilon\}$ and
 - ▶ $Z, Y_1, Y_2 \dots Y_n \in \Gamma$,

P contains rules

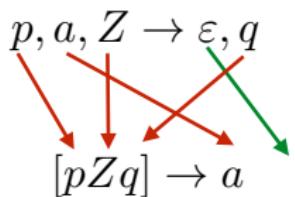

$$[pZq_n] \rightarrow a[qY_1q_1][q_1Y_2q_2] \dots [q_{n-1}Y_nq_n]$$

for all possible combinations of states $q_1, q_2, \dots, q_n \in Q$.

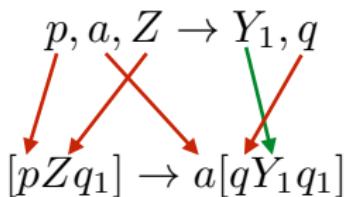

PDA to grammar illustrated

Special case: $n = 0$

Special case: $n = 1$

Exercise: transformation of PDA into grammar

$$\mathcal{A} = (Q, \Sigma, \Gamma, \Delta, 0, Z)$$

► $Q = \{0, 1\}$

► $\Sigma = \{a, b\}$

► $\Gamma = \{A, Z\}$

► $\Delta :$

$$0 \quad \varepsilon \quad Z \rightarrow \varepsilon \quad 0$$

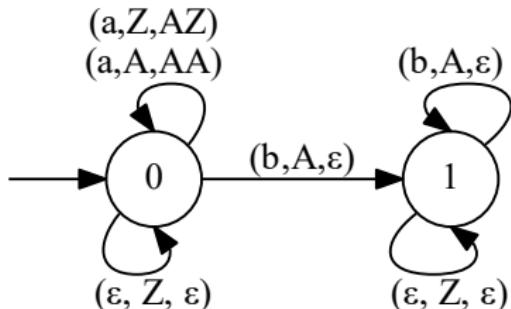

$$0 \quad a \quad Z \rightarrow AZ \quad 0$$

$$0 \quad a \quad A \rightarrow AA \quad 0$$

$$0 \quad b \quad A \rightarrow \varepsilon \quad 1$$

$$1 \quad b \quad A \rightarrow \varepsilon \quad 1$$

$$1 \quad \varepsilon \quad Z \rightarrow \varepsilon \quad 1$$

- Transform \mathcal{A} into a grammar $G_{\mathcal{A}}$ (and reduce $G_{\mathcal{A}}$).
- Show how $G_{\mathcal{A}}$ produces the words ε , ab , and $aabb$.

Solution

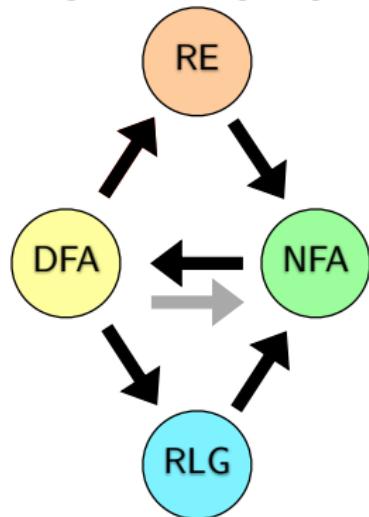

Bonus Exercises/Homework

- ▶ Assume $\Sigma = \{a, b\}$.
 - ▶ Find a PDA A_1 that accepts $L_1 = \{w \in \Sigma^* \mid |w|_a = |w|_b\}$.
 - ▶ Give an accepting run of A_1 on $abbaaa$.
- ▶ Assume $\Sigma = \{a, b\}$.
 - ▶ Find a PDA A_2 that accepts $L_2 = \{w \in \Sigma^* \mid |w|_a < |w|_b\}$.
 - ▶ Give an accepting run of A_2 on $bbbaaaabb$.
- ▶ Assume $\Sigma = \{a, b, c\}$.
 - ▶ Find a PDA A_3 that accepts
 $L_3 = \{w \in \Sigma^* \mid |w| \text{ is odd and } w[(|w| + 1)/2] = a\}$ (the middle symbol is an a)
 - ▶ Give an accepting run of A_3 on $cccaabb$.
- ▶ Assume $\Sigma = \{a, b, c\}$.
 - ▶ Find a PDA A_4 that accepts $L_4 = \{a^n b^m c^o \mid n, m, o \in \mathbb{N}, n = m + o\}$
 - ▶ Give an accepting run of A_4 on $aacc$.

End lecture 14

Comparison: Regular vs. context-free languages

Regular languages

Context-free languages

For both language classes there are different but equivalent formal descriptions, supporting different arguments about the classes!

Beyond context-free languages

Theorem (Existence of non-context-free languages)

Let Σ be an alphabet. There are languages $L \subseteq \Sigma^$ such that there is no context-free grammar G with $L = L(G)$.*

- ▶ There are languages that are not context-free
 - ▶ e.g. $\{a^n b^n c^n \mid n \in \mathbb{N}\}$
 - ▶ ... but how do we show this?
- ▶ For regular languages: Pumping lemma
 - ▶ Finite automata must loop on long words
 - ▶ Loops can be repeated
 - ▶ Hence: A language than cannot be pumped is not regular
- ▶ For context-free languages?

Pumping-lemma for context-free languages

Idea:

- ▶ If a context-free grammar G can produce words of arbitrary length, there is least one **repeated NTS** in the derivation
 - ▶ If there are n rules in the grammar, at least one rule has to be used more than once in a derivation of length $n + 1$
 - ▶ Slightly stronger arguments (based on $|N|$ instead of $|P|$ are possible)
- ▶ Hence there is a derivation $A \implies^* vAx$ for $v, x \in (\Sigma \cup \Gamma)^*$
 - ▶ ... and we can repeat this part of the derivation
$$A \implies^* vAx \implies^* vvAxx \implies^* vvvAxxx$$
 - ▶ If G has no chain rules, at least one of v, x is non-empty

Pumping Lemma I vs. Pumping Lemma II:

- ▶ PL I (regular languages)
 - ▶ Argument based on accepting automaton
 - ▶ Finite automaton must loop on sufficiently long word
 - ▶ One non-empty segment can be pumped
- ▶ PL II (context-free languages)
 - ▶ Argument based on generating grammar
 - ▶ At least one non-terminal must repeat in sufficiently long derivation
 - ▶ Two segments around this NTS can be pumped in parallel, at least one of which is non-empty

Pumping Lemma II

Theorem (Pumping-Lemma for context-free languages)

Let L be a language generated by a context-free grammar $G_L = (N, \Sigma, P, S)$ without contracting rules or chain rules. Let $m = |N|$, r be the maximum length of the rhs of a rule in P , and $k = r^{m+1}$. Then:
For every $s \in L$ with $|s| > k$ there exists a segmentation $u \cdot v \cdot w \cdot x \cdot y = s$ such that

- 1 $vx \neq \varepsilon$
- 2 $|vwx| \leq k$
- 3 $u \cdot v^h \cdot w \cdot x^h \cdot y \in L$ for every $h \in \mathbb{N}$.

- ▶ Holds for $\{a^n b^n\}$, but not for $\{a^n b^n c^n\}$.
- ▶ $\{a^n b^n c^n\}$ is not context-free, but context-sensitive, as we have seen before.

Group Exercise: $a^n b^n c^n$

Use the Pumping Lemma II to show that $L = \{a^n b^n c^n \mid n \in \mathbb{N}\}$ is not context-free.

Closure properties

Theorem (Closure under $\cup, \cdot, ^*$)

The class of context-free languages is closed under union, concatenation, and Kleene star.

For context-free grammars

$$G_1 = (N_1, \Sigma, P_1, S_1) \quad \text{and} \quad G_2 = (N_2, \Sigma, P_2, S_2)$$

with $N_1 \cap N_2 = \{\}$ (rename NTSs if needed), let S be a new start symbol.

- ▶ for $L(G_1) \cup L(G_2)$, add productions $S \rightarrow S_1, S \rightarrow S_2$.
- ▶ for $L(G_1) \cdot L(G_2)$, add production $S \rightarrow S_1S_2$.
- ▶ for $L(G_1)^*$, add productions $S \rightarrow \varepsilon, S \rightarrow S_1S$.

Closure properties (cont.)

Theorem (Closure under \cap)

Context-free languages are not closed under intersection.

Otherwise, $\{a^n b^n c^n\}$ would be context-free:

- ▶ $\{a^n b^n c^m\}$ is context-free
- ▶ $\{a^m b^n c^n\}$ is context-free
- ▶ $\{a^n b^n c^n\} = \{a^n b^n c^m\} \cap \{a^m b^n c^n\}$

Exercise: closure properties

- 1 Define context-free grammars for $L_1 = \{a^n b^n c^m \mid n, m \geq 0\}$ and $L_2 = \{a^m b^n c^n \mid n, m \geq 0\}$.
- 2 Use L_1 , L_2 and the known closure properties to show that context-free languages are not closed under complement.

Decision problems: word problem

Theorem (Word problem for cf. languages)

*For a word w and a context-free grammar G , it is **decidable** whether $w \in L(G)$ holds.*

Proof.

The CYK algorithm decides the word problem. □

Decision problems: emptiness problem

Theorem (Emptiness problem for cf. languages)

For a context-free grammar G , it is **decidable** if $L(G) = \{\}$ holds.

Proof.

Let $G = (N, \Sigma, P, S)$.

Iteratively compute **productive** NTSs, i.e. symbols that produce terminal words as follows:

- 1 let $Z = \Sigma$
- 2 add all symbols A to Z for which there is a rule $A \rightarrow \beta$ with $\beta \in Z^*$
- 3 repeat step 2 until no further symbols can be added
- 4 $L(G) = \{\}$ iff $S \notin Z$.

Decision problems: equivalence problem

Theorem (Equivalence problem for cf. languages)

*For context-free grammars G_1, G_2 , it is **undecidable** if $L(G_1) = L(G_2)$ holds.*

This follows from undecidability of Post's Correspondence Problem.

- ▶ A PCP can be encoded in grammars such that the PCP has a solution if and only if the two grammars are equivalent
- ▶ Since the PCP is undecidable, so is the equivalence problem
- ▶ Detail? Who needs details?

Summary: context-free languages

- ▶ characterised by
 - ▶ context-free grammars
 - ▶ pushdown automata
- ▶ closure properties
 - ▶ closed under $\cup, *, \cdot$
 - ▶ not closed under $\cap, \bar{\cdot}$
- ▶ decision problems
 - ▶ decidable: $w \in L(G), L(G) = \{\}$ (Chomsky NF, CYK algorithm)
 - ▶ undecidable: $L(G_1) = L(G_2)$
- ▶ can describe nested dependencies
 - ▶ structure of programming languages
 - ▶ natural language processing
- ▶ in compilers, these features are used by parsers (next chapter)

Parsing: Motivation

Formal grammars describe formal languages

- ▶ A grammar has a set of rules
- ▶ Rules replace words with words
- ▶ A word that can be derived from the start symbol belongs to the language of the grammar

**In the concrete case of programming languages,
“words of the language” are syntactically correct programs!**

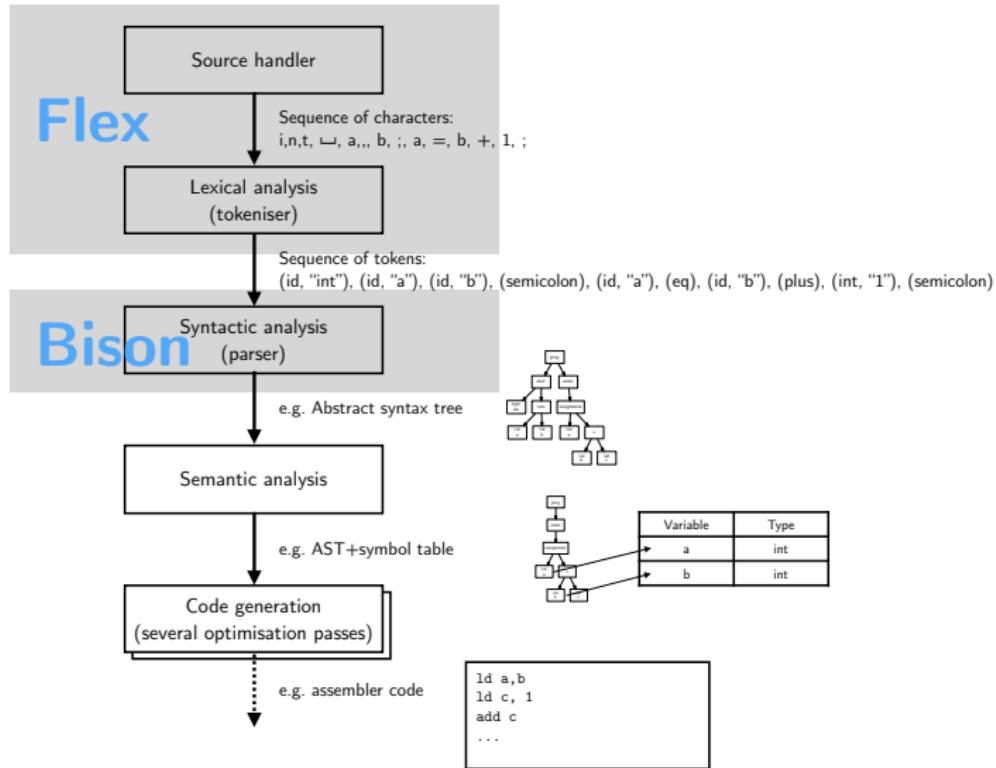

Grammars in Practice

- ▶ Most programming languages are described by context-free grammars (with extra “semantic” constraints)
- ▶ Grammars **generate** languages
- ▶ PDAs and e.g. CYK-Parsing **recognize** words
- ▶ For compiler we need to ...
 - ▶ identify correct programs
 - ▶ and understand their structure!

Lexing and Parsing

- ▶ **Lexer:** Breaks programs into tokens
 - ▶ Smallest parts with semantic meaning
 - ▶ Can be recognized by regular languages/patterns
 - ▶ Example: 1, 2, 53 are all Integers
 - ▶ Example: i, handle, stream are all Identifiers
 - ▶ Example: >, >=, * are all individual operators
- ▶ **Parser:** Recognizes program structure
 - ▶ Language described by a grammar that has token types as terminals, not individual characters
 - ▶ Parser builds **parse tree**

Automatisation with Bison

YACC/Bison

- ▶ Yacc - Yet Another Compiler Compiler
 - ▶ Originally written ≈1971 by Stephen C. Johnson at AT&T
 - ▶ LALR parser generator
 - ▶ Translates grammar into syntax analyser

- ▶ GNU Bison
 - ▶ Written by Robert Corbett in 1988
 - ▶ Yacc-compatibility by Richard Stallman
 - ▶ Output languages now C, C++, Java
- ▶ Yacc, Bison, BYacc, ... mostly compatible (POSIX P1003.2)

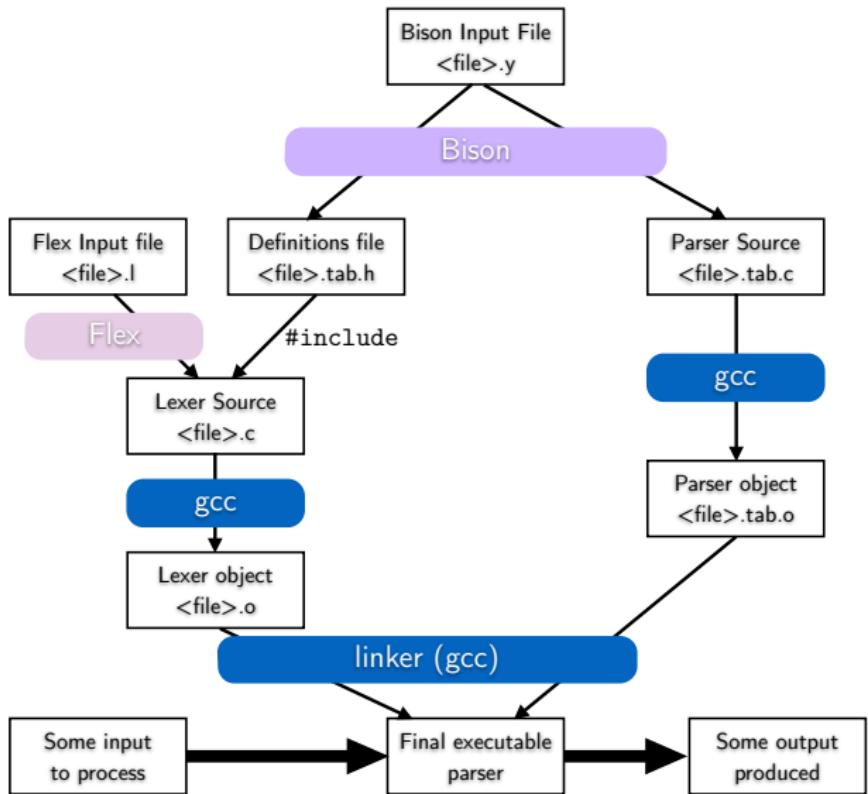

Yacc/Bison Background

- ▶ By default, Bison constructs a **1 token Look-Ahead Left-to-right Rightmost-derivation** or LALR(1) parser
 - ▶ Input tokens are processed **left**-to-right
 - ▶ Shift-reduce parser:
 - ▶ **Stack** holds tokens (terminals) and non-terminals
 - ▶ Tokens are **shifted** from input to stack. If the top of the stack contains symbols that represent the right hand side (RHS) of a grammar rule, the content is **reduced** to the LHS
 - ▶ Since input is reduced left-to-right, this corresponds to a **rightmost** derivation
 - ▶ Ambiguities are solved via look-ahead and special rules
 - ▶ If input can be reduced to start symbol, success!
 - ▶ Error otherwise
- ▶ LALR(1) is efficient in time and memory
 - ▶ Can parse “all reasonable languages”
 - ▶ For unreasonable languages, Bison (but not Yacc) can also construct **GLR** (General LR) parsers
 - ▶ Try all possibilities with back-tracking
 - ▶ Corresponds to the **non-determinism** of stack machines

Yacc/Bison Overview

- ▶ Bison reads a specification file and converts it into (C) code of a parser
- ▶ Specification file: Declarations, grammar rules with actions, support code
 - ▶ Declarations: C declarations and data model, token names, associated values, includes
 - ▶ Grammar rules: Non-terminal with alternatives, **action** associated with each alternative
 - ▶ Support code: e.g. `main()` function, error handling...
 - ▶ Syntax similar to (F)lex
 - ▶ Sections separated by `%%`
 - ▶ Special commands start with `%`
- ▶ Bison generates function `yyparse()`
- ▶ Bison needs function `yylex()`
 - ▶ Usually provided via (F)lex

Yacc/Bison workflow

Development time

Execution time

Example task: Desk calculator

- ▶ Desk calculator
 - ▶ Reads algebraic expressions and assignments
 - ▶ Prints result of expressions
 - ▶ Can store values in **registers** R0-R99
- ▶ Example session:

```
[Shell] ./scicalc
R10=3*(5+4)
> RegVal: 27.000000
(3.1415*R10+3)
> 87.820500

R9=(3.1415*R10+3)
> RegVal: 87.820500

R9+R10
> 114.820500
...
...
```

Abstract grammar for desk calculator (partial)

$$G_{DC} = (N, \Sigma, P, S)$$

- ▶ $\Sigma = \{\text{PLUS, MULT, ASSIGN, OPENPAR, CLOSEPAR, REGISTER, FLOAT, ...}\}$
 - ▶ Some terminals are single characters (+, =, ...)
 - ▶ Others are complex R10, 1.3e7
 - ▶ Terminals (“tokens”) are generated by the lexer
- ▶ $N = \{\text{stmt, assign, expr, term, factor, ...}\}$

▶ $P :$

stmt	\rightarrow	assign
		expr
assign	\rightarrow	REGISTER ASSIGN expr
expr	\rightarrow	expr PLUS term
		term
term	\rightarrow	term MULT factor
		factor
factor	\rightarrow	REGISTER
		FLOAT
		OPENPAR expr CLOSEPAR

▶ $S :$

- ▶ For a single statement, $S = \text{stmt}$
- ▶ In practice, we need to handle sequences of statements and empty input lines (not reflected in the grammar)

Parsing statements (1)

- ▶ Example string: R10 = (4.5+3*7)
- ▶ Tokenized: REGISTER ASSIGN OPENPAR FLOAT PLUS
FLOAT MULT FLOAT CLOSEPAR
 - ▶ In the following abbreviated R, A, O, F, P, F, M, F, C
- ▶ Parsing state:
 - ▶ Unread input (left column)
 - ▶ Current stack (middle column, top element on right)
 - ▶ How state was reached (right column)
- ▶ Parsing:

Input	Stack	Comment
R A O F P F M F C		Start
A O F P F M F C	R	Shift R to stack
O F P F M F C	R A	Shift A to stack
F P F M F C	R A O	Shift O to stack
P F M F C	R A O F	Shift F to stack
P F M F C	R A O factor	Reduce F
P F M F C	R A O term	Reduce factor

...

Parsing statements (2)

R A O F P F M F C		Start
A O F P F M F C	R	Shift R to stack
O F P F M F C	R A	Shift A to stack
F P F M F C	R A O	Shift O to stack
P F M F C	R A O F	Shift F to stack
P F M F C	R A O factor	Reduce F
P F M F C	R A O term	Reduce factor
P F M F C	R A O expr	LA! Reduce term
F M F C	R A O expr P	Shift P
M F C	R A O expr P F	Shift F
M F C	R A O expr P factor	Reduce F
M F C	R A O expr P term	Reduce factor
F C	R A O expr P term M	LA! Shift M
C	R A O expr P term M F	Shift F
C	R A O expr P term M factor	Reduce F
C	R A O expr P term	Reduce tMf
C	R A O expr	Reduce ePt
	R A O expr C	Shift C
	R A factor	Reduce OeC
	R A term	Reduce factor
	R A expr	Reduce term
	assign	Reduce RAe
	stmt	Reduce assign

Lexer interface

- ▶ Bison parser requires `yylex()` function
- ▶ `yylex()` returns **token**
 - ▶ Token text is defined by regular expression pattern
 - ▶ Tokens are encoded as integers
 - ▶ Symbolic names for tokens are defined by Bison in generated header file
 - ▶ By convention: Token names are all CAPITALS
- ▶ `yylex()` provides optional **semantic value** of token
 - ▶ Stored in global variable `yyval`
 - ▶ Type of `yyval` defined by Bison in generated header file
 - ▶ Default is `int`
 - ▶ For more complex situations often a `union`
 - ▶ For our example: Union of double (for floating point values) and integer (for register numbers)

%%
```

Data model of desk calculator

- ▶ Desk calculator has simple state
 - ▶ 100 floating point registers
 - ▶ R0-R99
- ▶ Represented in C as array of doubles:

```
#define MAXREGS 100  
  
double regfile[MAXREGS];
```

- ▶ Needs to be initialized in support code

Bison code for desk calculator: Declarations

```
% {  
    #include <stdio.h>  
  
    #define MAXREGS 100  
  
    double regfile[MAXREGS];  
  
    extern int yyerror(char* err);  
    extern int yylex(void);  
}  
  
%union {  
    double val;  
    int     regno;  
}
```

Bison code for desk calculator: Tokens

```
%start stmtseq

%left PLUS
%left MULT
%token ASSIGN
%token OPENPAR
%token CLOSEPAR
%token NEWLINE
%token REGISTER
%token FLOAT
%token ERROR

%%
```

Actions in Bison

- ▶ Bison is based on syntax rules with associated actions
 - ▶ Whenever a **reduce** is performed, the action associated with the rule is executed
- ▶ Actions can be arbitrary C code
- ▶ Frequent: **semantic actions**
 - ▶ The action sets a **semantic value** based on the semantic value of the symbols reduced by the rule
 - ▶ For terminal symbols: Semantic value is `yytval` from Flex
 - ▶ Semantic actions have “historically valuable” syntax
 - ▶ Value of reduced symbol: `$$`
 - ▶ Value of first symbol in syntax rule body: `$1`
 - ▶ Value of second symbol in syntax rule body: `$2`
 - ▶ ...
 - ▶ Access to named components: `$<val>1`

Bison code for desk calculator: Grammar (1)

```
stmtseq: /* Empty */
        | NEWLINE stmtseq          { }
        | stmt   NEWLINE stmtseq { }
        | error  NEWLINE stmtseq { }; /* After an error,
start afresh */
```

- ▶ Head: sequence of statements
- ▶ First body line: Skip empty lines
- ▶ Second body line: separate current statement from rest
- ▶ Third body line: After parse error, start again with new line

Bison code for desk calculator: Grammar (2)

```
stmt: assign {printf("> RegVal: %f\n", $<val>1);} ;  
          |expr {printf("> %f\n", $<val>1);} ;  
  
assign: REGISTER ASSIGN expr {regfile[$<regno>1] = $<val>3;  
                           $<val>$ = $<val>3;} ;  
  
expr: expr PLUS term {$<val>$ = $<val>1 + $<val>3;} ;  
     | term {$<val>$ = $<val>1;} ;  
  
term: term MULT factor {$<val>$ = $<val>1 * $<val>3;} ;  
     | factor {$<val>$ = $<val>1;} ;  
  
factor: REGISTER {$<val>$ = regfile[$<regno>1];} ;  
       | FLOAT {$<val>$ = $<val>1;} ;  
       | OPENPAR expr CLOSEPAR {$<val>$ = $<val>2;} ;
```

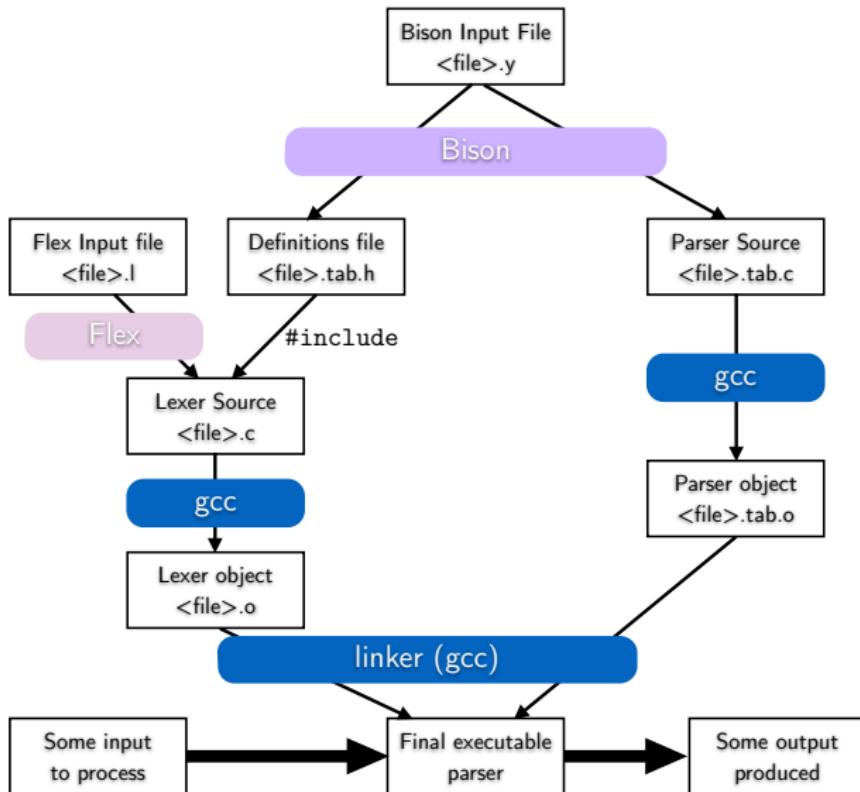

Bison code for desk calculator: Support code

```
int yyerror(char* err)
{
    printf("Error: %s\n", err);
    return 0;
}

int main (int argc, char* argv[])
{
    int i;

    for(i=0; i<MAXREGS; i++)
    {
        regfile[i] = 0.0;
    }
    return yyparse();
}
```

Bison workflow and dependencies

Building the calculator

- 1 Generate parser C code and include file for lexer
 - ▶ `bison -d scicalcparse.y`
 - ▶ Generates `scicalcparse.tab.c` and `scicalcparse.tab.h`
- 2 Generate lexer C code
 - ▶ `flex -t scicalclex.l > scicalclex.c`
- 3 Compile lexer
 - ▶ `gcc -c -o scicalclex.o scicalclex.c`
- 4 Compile parser and support code
 - ▶ `gcc -c -o scicalcparse.tab.o scicalcparse.tab.c`
- 5 Link everything
 - ▶ `gcc scicalclex.o scicalcparse.tab.o -o scicalc`
- 6 Fun!
 - ▶ `./scicalc`

Exercise: calculator

- ▶ Exercise 1:
 - ▶ Go to <http://wwwlehre.dhbw-stuttgart.de/~sschulz/fla2017.html>
 - ▶ Download scicalcparse.y and scicalclex.l
 - ▶ Build the calculator
 - ▶ Run and test the calculator
- ▶ Exercise 2:
 - ▶ Add support for division and subtraction /, -
 - ▶ Add support for unary minus (the negation operator -)

Derivations

Definition (derivation)

For a grammar G , a **derivation** of a word w_n in $L(G)$ is a sequence $S \Rightarrow w_1 \Rightarrow \dots \Rightarrow w_n$ where S is the start symbol, and each w_i is generated from its predecessor by application of a production of the grammar

Example: derivation

Example (well-formed expressions over $x, +, *.(,)$)

Let $G_E = (N, \Sigma, P, E)$ with

- ▶ $N = \{E\}$
- ▶ $\Sigma = \{(,), +, *, x\}$
- ▶ $P:$

- 1 $E \rightarrow x$
- 2 $E \rightarrow (E)$
- 3 $E \rightarrow E + E$
- 4 $E \rightarrow E * E$

The following is a derivation of $x + x + x * x$ (with the replaced symbol printed bold):

$$\begin{aligned} & \mathbf{E} \\ \Rightarrow & \mathbf{E} + E \\ \Rightarrow & E + E + \mathbf{E} \\ \Rightarrow & \mathbf{E} + E + E * E \\ \Rightarrow & x + \mathbf{E} + E * E \\ \Rightarrow & x + x + \mathbf{E} * E \\ \Rightarrow & x + x + x * \mathbf{E} \\ \Rightarrow & x + x + x * x \end{aligned}$$

Rightmost and leftmost Derivations

Definition (rightmost/leftmost)

- ▶ A derivation is called a **rightmost** derivation, if at any step it replaces the **rightmost** non-terminal in the current word.
- ▶ A derivation is called a **leftmost** derivation, if at any step it replaces the **leftmost** non-terminal in the current word.

Example

- ▶ The derivation on the previous slide is neither leftmost nor rightmost.
- ▶ A **rightmost derivation** is:
$$\begin{aligned} E &\Rightarrow E + E \Rightarrow E + E + E \Rightarrow E + E + E * E \Rightarrow E + E + E * x \Rightarrow \\ &E + E + x * x \Rightarrow E + x + x * x \Rightarrow x + x + x * x \end{aligned}$$

Parse trees

Definition (parse tree)

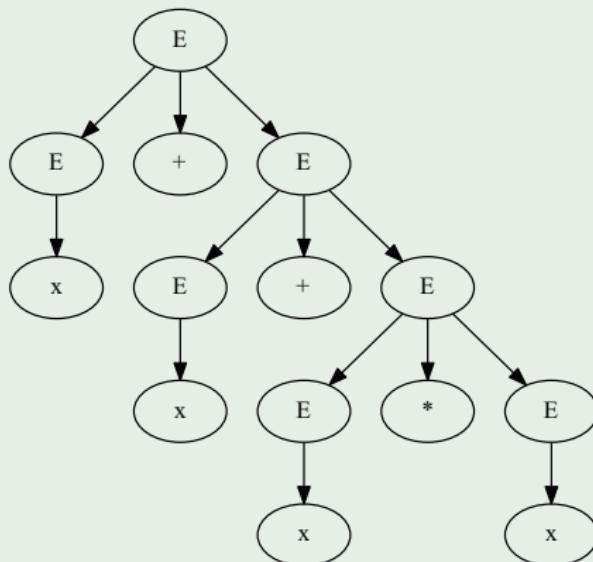

A **parse tree** for a derivation in a grammar $G = (N, \Sigma, P, S)$ is an ordered, labelled tree with the following properties:

- ▶ Each node is labelled with a symbol from $N \cup \Sigma$
 - ▶ The root of the tree is labelled with the start symbol S .
 - ▶ Each inner node is labelled with a single non-terminal symbol from V_N
 - ▶ If an inner node with label A has children labelled with symbols $\alpha_1, \dots, \alpha_n$, then there is a production $A \rightarrow \alpha_1 \dots \alpha_n$ in P .
-
- ▶ The parse tree represents a derivation of the word formed by the labels of the leaf nodes
 - ▶ It abstracts from the order in which productions are applied.

Example: parse trees

Example

The derivation $\mathbf{E} \Rightarrow E + \mathbf{E} \Rightarrow E + E + \mathbf{E} \Rightarrow E + E + E * \mathbf{E} \Rightarrow E + E + \mathbf{E} * x \Rightarrow E + \mathbf{E} + x * x \Rightarrow \mathbf{E} + x + x * x \Rightarrow x + x + x * x$ can be represented by a sequence of parse trees:

Ambiguity

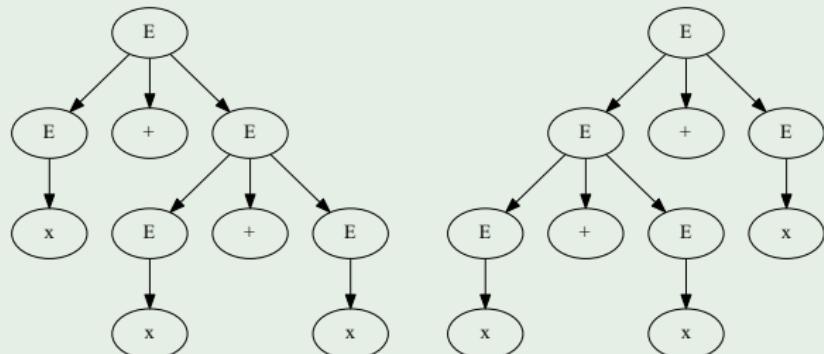

Definition (ambiguous)

A grammar $G = (N, \Sigma, P, S)$ is **ambiguous** if it has multiple different parse trees for a word w in $L(G)$.

Example

G_E is ambiguous since it has several parse trees for $x + x + x$.

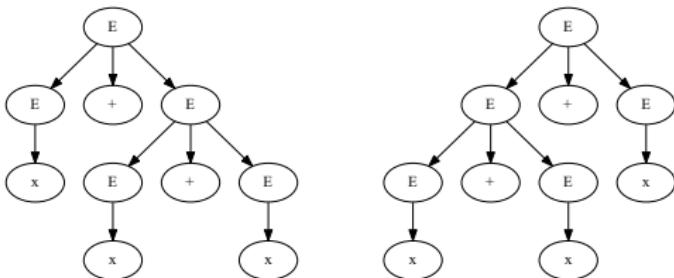

- 1 $E \rightarrow x$
- 2 $E \rightarrow (E)$
- 3 $E \rightarrow E + E$
- 4 $E \rightarrow E * E$

Exercise: Ambiguity is worse...

Consider the grammar G_E and its parse trees for $x + x + x$.

- 1 $E \rightarrow x$
- 2 $E \rightarrow (E)$
- 3 $E \rightarrow E + E$
- 4 $E \rightarrow E * E$

- ▶ Provide a rightmost derivation for the right tree.
- ▶ Provide a rightmost derivation for the left tree.
- ▶ Provide a leftmost derivation for the left tree.
- ▶ Provide a leftmost derivation for the right tree.

Exercise: Eliminating Ambiguity

Consider G_E with the following productions:

- 1 $E \rightarrow x$
- 2 $E \rightarrow (E)$
- 3 $E \rightarrow E + E$
- 4 $E \rightarrow E * E$

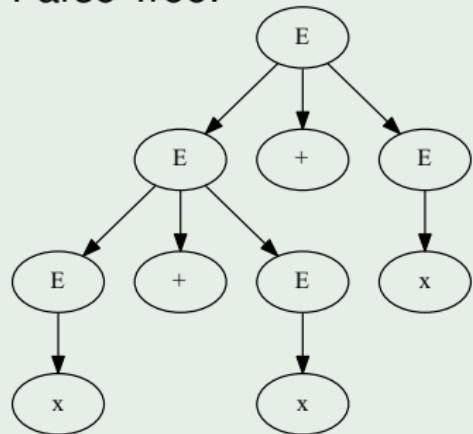

Define a grammar G' with $L(G) = L(G')$ that is not ambiguous, that respects that $*$ has a higher precedence than $+$, and that respects left-associativity for all operators.

Abstract Syntax Trees

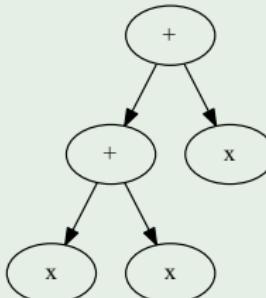

- ▶ Abstract Syntax Trees represent the structure of a derivation without the specific details
- ▶ Think: “Parse trees without redundant syntactic elements”

Example

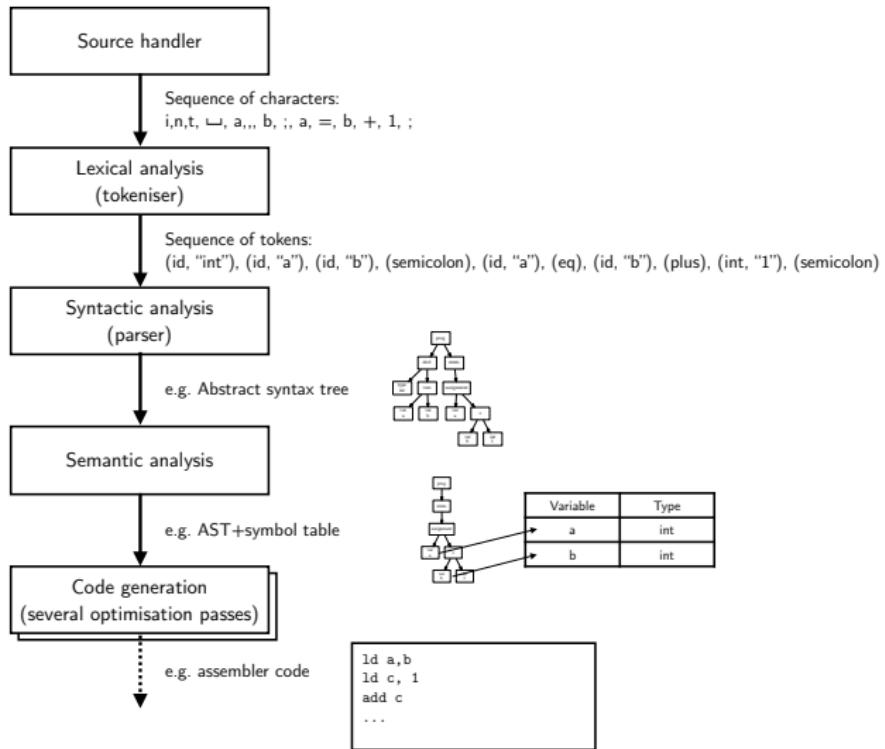

Parse Tree:

Corresponding AST:

High-Level Architecture of a Compiler

Syntactic Analysis/Parsing

- ▶ Description of the language with a context-free grammar
- ▶ Parsing:
 - ▶ Try to build a parse tree/abstract syntax tree (AST)
 - ▶ Parse tree unambiguously describes structure of a program
 - ▶ AST reflects abstract syntax (can e.g. drop parenthesis)
- ▶ Methods:
 - ▶ Manual recursive descent parser
 - ▶ Automatic with a table-driven bottom-up parser

Result: Abstract Syntax Tree

Semantic Analysis

- ▶ Analyze static properties of the program
 - ▶ Which variable has which type?
 - ▶ Are all expressions well-typed?
 - ▶ Which names are defined?
 - ▶ Which names are referenced?
- ▶ Core tool: Symbol table

Result: Annotated AST

Optimization

- ▶ Transform Abstract Syntax Tree to generate better code
 - ▶ Smaller
 - ▶ Faster
 - ▶ Both
- ▶ Mechanisms
 - ▶ Common sub-expression elimination
 - ▶ Loop unrolling
 - ▶ Dead code/data elimination
 - ▶ ...

Result: Optimized AST

Code Generation

- ▶ Convert optimized AST into low-level code
- ▶ Target languages:
 - ▶ Assembly code
 - ▶ Machine code
 - ▶ VM code (z.B. JAVA byte-code, p-Code)
 - ▶ C (as a “portable assembler”)
 - ▶ ...

Result: Program in target language

Summary: parsers

Parsers

- ▶ recognise structure of programs
- ▶ receive **tokens** from scanner
- ▶ construct **parse tree** and symbol table
- ▶ common: **shift-reduce** parsing

Bison

- ▶ receives tokens and their semantic values from Flex
- ▶ uses grammar rules to perform semantic actions
- ▶ uses look-ahead to resolve conflicts

Turing Machines

Turing Machine: Motivation

Four classes of languages described by grammars and equivalent machine models:

- 1 regular languages \leadsto finite automata
- 2 context-free languages \leadsto pushdown automata
- 3 context-sensitive languages \leadsto ?
- 4 Type-0-languages \leadsto ?

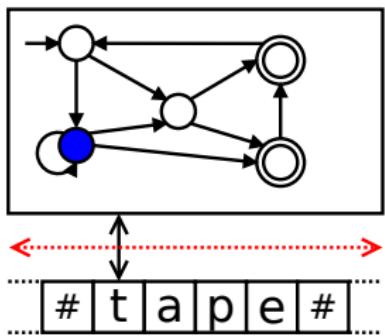

We need a machine model that is more powerful than PDAs:
Turing Machines

Turing Machine: history

- ▶ proposed in 1936 by Alan Turing
 - ▶ paper: *On computable numbers, with an application to the Entscheidungsproblem*
 - ▶ uses the TM to show that satisfiability of first-order formulas is **undecidable**
- ▶ model of a **universal computer**
 - ▶ very simple (and thus easy to describe formally)
 - ▶ but as powerful as any conceivable machine

Turing Machine: conceptual model

- ▶ medium: unlimited **tape** (bidirectional)
 - ▶ initially contains input (and blanks #)
 - ▶ TM can read and **write** tape
 - ▶ TM can **move arbitrarily** over tape
 - ▶ serves for input, working, output
 - ▶ **output** possible
- ▶ transition relation
 - ▶ read and write current position
 - ▶ moving instructions (l, r, n)
- ▶ acceptance condition
 - ▶ **final state** is reached
 - ▶ no transitions possible
- ▶ commonalities with FA
 - ▶ control unit (finite set of states),
 - ▶ initial and final states
 - ▶ input alphabet

Transitions in Turing Machines

$$\Delta \subseteq Q \times \Gamma \times \Gamma \times \{l, n, r\} \times Q$$

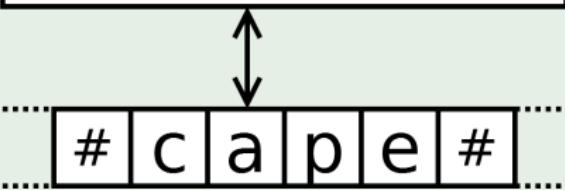

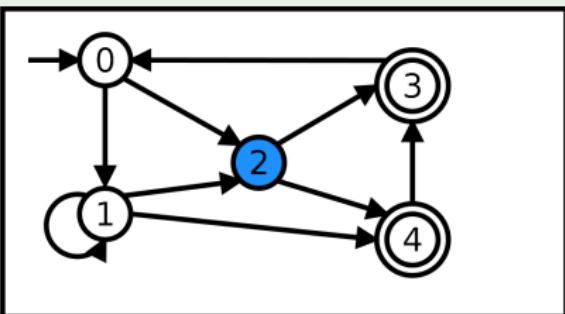

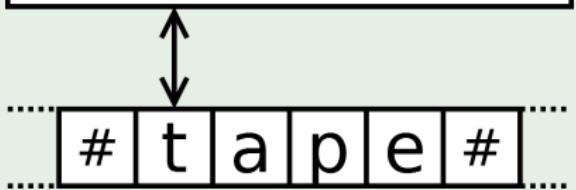

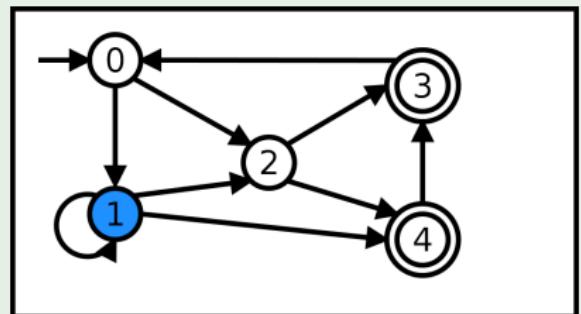

- ▶ TM is in state
- ▶ reads tape symbol from current position
- ▶ writes tape symbol on current position
- ▶ moves to left, right, or stays
- ▶ goes into a new state

A transition p, a, b, l, q can also be written as

$$p \quad a \quad \rightarrow \quad b \quad l \quad q$$

Example: transition

Example (transition 1, $t \rightarrow c, r, 2$)

Turing Machine: formal definition

Definition (Turing Machine)

A **Turing Machine** (TM) is a 6-tuple $(Q, \Sigma, \Gamma, \Delta, q_0, F)$ where

- ▶ Q, Σ, q_0, F are defined as for NFAs,
- ▶ $\Gamma \supseteq \Sigma \cup \{\#\}$ is the **tape alphabet**,
including at least Σ and the blank symbol,
- ▶ $\Delta \subseteq Q \times \Gamma \times \Gamma \times \{l, n, r\} \times Q$ is the transition relation.

If Δ contains at most one transition (p, a, b, d, q) for each pair $(p, a) \in Q \times \Sigma$, the TM is called **deterministic**. The transition **function** is then denoted by δ .

Note:

- ▶ Γ (the tape alphabet) can contain additional characters
- ▶ This does not increase the power, but makes finding TMs easier

Configurations of TMs

Definition (configuration)

A configuration $c = \alpha q \beta$ of a Turing Machine is given by

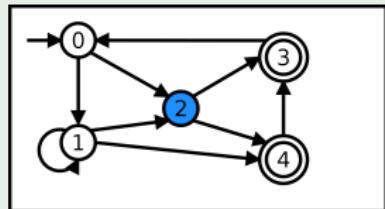

- ▶ the current state q
- ▶ the tape content α on the left of the read/write head
(except unlimited # sequences)
- ▶ the tape content β starting with the position of the head
(except unlimited # sequences)

A configuration $c = \alpha q \beta$ is accepting if $q \in F$.

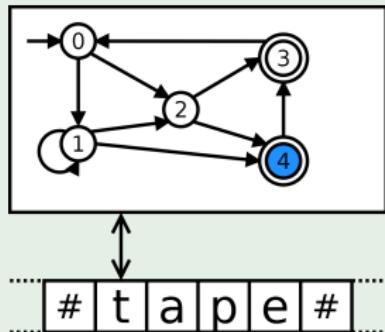

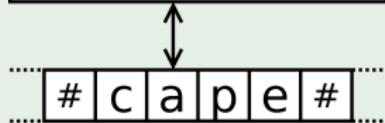

A configuration c is a stop configuration if there are no transitions from c .

Example: configuration

Example (configurations)

- ▶ This TM is in the configuration *c2ape*.

- ▶ The configuration *4tape* is accepting.
- ▶ If there are no transitions $4, t \rightarrow \dots$, *4tape* also is a stop configuration.

Computations of TMs

Definition (computation, acceptance)

A **computation** of a TM \mathcal{M} on a word w is a sequence of configurations (according to the transition function) of configurations of \mathcal{M} , starting from q_0w .

\mathcal{M} **accepts** w if there exists a computation of \mathcal{M} on w that leads to an accepting stop configuration.

Exercise: Turing Machines

Let $\Sigma = \{a, b\}$ and $L = \{w \in \Sigma^* \mid |w|_a \text{ is even}\}.$

- ▶ Give a TM \mathcal{M} that accepts (exactly) the words in L .
- ▶ Give the computation of \mathcal{M} on the words $abbab$ and $bbab$.

Example: TM for $a^n b^n c^n$

$\mathcal{M} = (Q, \Sigma, \Gamma, \Delta, \text{start}, \{f\})$ with

- ▶ $Q = \{\text{start}, \text{findb}, \text{findc}, \text{check}, \text{back}, \text{end}, f\}$
- ▶ $\Sigma = \{a, b, c\}$ and $\Gamma = \Sigma \cup \{\#, x, y, z\}$

state	read	write	move	state	state	read	write	move	state
start	#	#	n	f	back	z	z		back
start	a	x	r	findb	back	b	b		back
findb	a	a	r	findb	back	y	y		back
findb	y	y	r	findb	back	a	a		back
findb	b	y	r	findc	back	x	x	r	start
findc	b	b	r	findc	end	z	z		end
findc	z	z	r	findc	end	y	y		end
findc	c	z	r	check	end	x	x		end
check	c	c		back	end	#	#	n	f
check	#	#		end					

Exercise: Turing Machines (2)

- a) Simulate the computations of \mathcal{M} on $aabbcc$ and $aabc$.
- b) Develop a Turing Machine \mathcal{P} accepting $L_{\mathcal{P}} = \{wcw \mid w \in \{a, b\}^*\}$.
- c) How do you have to modify \mathcal{P} if you want to recognise inputs of the form ww ?

Turing Machines with several tapes

- ▶ A k -tape TM has k tapes on which the heads can move independently.
- ▶ $\Delta \subseteq Q \times \Gamma^k \times \Gamma^k \times \{r, l, n\}^k \times Q$
- ▶ It is possible to simulate a k -tape TM with a (1-tape) TM:
 - ▶ use alphabet $\Gamma^k \times \{X, \#\}^k$
 - ▶ the first k language elements encode the tape content, the remaining ones the positions of the heads.

Nondeterminism

Reminder

- ▶ just like FAs and PDAs, TMs can be deterministic or non-deterministic, depending on the transition relation.
- ▶ for non-deterministic TMs, the machine accepts w if there exists a sequence of transitions leading to an accepting stop configuration.

Simulating non-deterministic TMs

Theorem (equivalence of deterministic and non-deterministic TMs)

Deterministic TMs can simulate computations of non-deterministic TMs; i.e. they describe the same class of languages.

Proof.

Use a 3-tape TM:

- ▶ tape 1 stores the input w
- ▶ tape 2 enumerates all possible sequences of non-deterministic choices (for all non-deterministic transitions)
- ▶ tape 3 encodes the computation on w with choices stored on tape 2.

Bonus Exercises

Selected Solutions

Turing Machines and unrestricted grammars

Theorem (equivalence of TMs and unrestricted grammars)

The class of languages that can be accepted by a Turing Machine is exactly the class of languages that can be generated by unrestricted Chomsky grammars.

Proof.

- 1 simulate grammar derivations with a TM
- 2 simulate a TM computation with a grammar

Simulating a Type-0-grammar G with a TM

Use a non-deterministic 2-tape TM:

- ▶ tape 1 stores input word w
- ▶ tape 2 simulates the derivations of G , starting with S
 - ▶ (non-deterministically) choose a position
 - ▶ if the word starting at the position, matches α of a rule $\alpha \rightarrow \beta$, apply the rule
 - ▶ move tape content if necessary
 - ▶ replace α with β
- ▶ compare content of tape 2 with tape 1
 - ▶ if they are equal, accept
 - ▶ otherwise continue

Simulating a TM with a Type-0-grammar

Goal: transform TM $\mathcal{A} = (Q, \Sigma, \Gamma, \Delta, q_0, F)$ into grammar G

Technical difficulty:

- ▶ \mathcal{A} receives word as input **at the start**, possibly modifies it, then possibly accepts.
 - ▶ G starts with S , applies rules, possibly generating w **at the end**.
-
- 1 generate initial configuration $q_0w \in \Sigma^*$ with blanks left and right
 - 2 simulate the computation of \mathcal{A} on w

$$(p, a, b, r, q) \rightsquigarrow pa \rightarrow bq$$

$$(p, a, b, l, q) \rightsquigarrow cpa \rightarrow qcb \text{ (for all } c \in \Gamma\text{)}$$

$$(p, a, b, n, q) \rightsquigarrow pa \rightarrow qb$$

- 3 if an accepting stop configuration is reached, recreate w
 - ▶ requires a more complex alphabet with a “backup track”

Turing Machines

Unrestricted Grammars

Linear Bounded Automata

Properties of Type-0-languages

Lecture-specific material

Bonus Exercises

Selected Solutions

Linear bounded automata

- ▶ context-sensitive grammars do not allow for contracting rules
- ▶ a **linear bounded automaton (LBA)** is a TM that only uses the space originally occupied by the input w .
- ▶ limits of w are indicated by markers that cannot be passed by the read/write head

...	>	i	n	p	u	t	<	...
-----	---	---	---	---	---	---	---	-----

Equivalence of cs. grammars and LBAs

Transformation of cs. grammar G into LBA:

- ▶ as for Type-0-grammar: use 2-tape-TM
 - ▶ input on tape 1
 - ▶ simulate operations of G on tape 2
- ▶ since the productions of G are non-contracting, words longer than w need not be considered

Transformation of LBA \mathcal{A} into cs. grammar:

- ▶ similar to construction for TM:
 - ▶ generate w without blanks
 - ▶ simulate operation of \mathcal{A} on w
 - ▶ rules are non-contracting ✓

Closure properties: regular operations

Theorem (closure under $\cup, \cdot, ^*$)

The class of languages described by context-sensitive grammars is closed under $\cup, \cdot, ^$.*

Proof.

Concatenation and Kleene-star are more complex than for cf. grammars because the context can influence rule applicability.

- ▶ rename NTSs (as for cf. grammars)
- ▶ only allow NTSs as context
- ▶ only allow productions of the kind
 - ▶ $N_1N_2 \dots N_k \rightarrow M_1M_2 \dots M_j$
 - ▶ $N \rightarrow a$

Closure properties: intersection and complement

Theorem (closure under \cap)

The class of context-sensitive languages is closed under intersection.

Proof.

- ▶ use a 2-tape-LBA
- ▶ simulate computation of \mathcal{A}_1 on tape 1, \mathcal{A}_2 on tape 2
- ▶ accept if both \mathcal{A}_1 and \mathcal{A}_2 accept

□

Theorem (closure under $\overline{\cdot}$)

The class of context-sensitive languages is closed under complement.

- ▶ shown in 1988

Context-sensitive grammars: decision problems

Theorem (Word problem for cs. languages)

The word problem for cs. languages is decidable.

Proof.

- ▶ N , Σ and P are finite
- ▶ rules are non-contracting
- ▶ for a word of length n only a finite number of derivations up to length n has to be considered.

Context-sensitive grammars: decision problems (cont')

Theorem (Emptiness problem for cs. languages)

The emptiness problem for cs. languages is undecidable.

Proof.

Also follows from undecidability of Post's correspondence problem. □

Theorem (Equivalence problem for cs. languages)

The equivalence problem for cs. languages is undecidable.

Proof.

If this problem was decidable for cs. languages, it would also be decidable for cf. languages (since every cf. language is also cs.). □

Bonus Exercises

Selected Solutions

The universal Turing Machine \mathcal{U}

- ▶ \mathcal{U} is a TM that simulates other Turing Machines
- ▶ since TMs have finite alphabets and state sets, they can be encoded by a (binary) alphabet by an encoding function $c()$
- ▶ Input:
 - ▶ encoding $c(\mathcal{A})$ of a TM \mathcal{A} on tape 1
 - ▶ encoding $c(w)$ of an input word w for \mathcal{A} on tape 2
- ▶ with input $c(\mathcal{A})$ and $c(w)$, \mathcal{U} behaves exactly like \mathcal{A} on w :
 - ▶ \mathcal{U} accepts iff \mathcal{A} acceptss
 - ▶ \mathcal{U} halts iff \mathcal{A} halts
 - ▶ \mathcal{U} runs forever if \mathcal{A} runs forever

Every solvable problem can be solved in software.

Operation of \mathcal{U}

- 1 encode initial configuration
 - ▶ tape on lhs of head
 - ▶ state
 - ▶ tape on rhs of head
- 2 use $c(\mathcal{A})$ to find a transition from the current configuration
- 3 modify the current configuration accordingly
- 4 accept if \mathcal{A} accepts
- 5 stop if \mathcal{A} stops
- 6 otherwise, continue with step 2

The Halting problem

Definition (halting problem)

For a TM $\mathcal{A} = (Q, \Sigma, \Gamma, q_0, \Delta, F)$ and a word $w \in \Sigma^*$, does \mathcal{A} halt (i.e. reach a stop configuration) with input w ?

Wanted: TMs $\mathcal{H}1$ and $\mathcal{H}2$, such that with input $c(\mathcal{A})$ and $c(w)$

- 1 $\mathcal{H}1$ accepts iff \mathcal{A} halts on w and
- 2 $\mathcal{H}2$ accepts iff \mathcal{A} does **not** halt on w .

decision procedure for HP: let $\mathcal{H}1$ and $\mathcal{H}2$ run in parallel

- 1 \mathcal{U} (almost) does what $\mathcal{H}1$ needs to do.
- 2 Difficult: $\mathcal{H}2$ needs to detect that \mathcal{A} does not terminate.
 - ▶ infinite tape \leadsto infinite number possible configurations
 - ▶ recognising repeated configurations not sufficient.

Undecidability of the halting problem

Assumption: there is a TM $\mathcal{H}2$ which, given $c(\mathcal{A})$ and $c(w)$ as input

- 1 accepts if \mathcal{A} does **not** halt with input w and
- 2 runs forever if \mathcal{A} halts with input w .

If $\mathcal{H}2$ exists, then there is also a TM \mathcal{S} accepting exactly those encodings of TMs that do **not** accept their own encoding

- 1 input: TM encoding $c(\mathcal{A})$ on tape 1
- 2 \mathcal{S} copies $c(\mathcal{A})$ to tape 2
- 3 afterwards \mathcal{S} operates like $\mathcal{H}2$

Computation of \mathcal{S} with input $c(\mathcal{A})$

Reminder: \mathcal{S} accepts $c(\mathcal{A})$ iff \mathcal{A} does **not** accept $c(\mathcal{A})$.

Case 1 \mathcal{S} accepts $c(\mathcal{S})$. This implies that \mathcal{S} does not halt on the input $c(\mathcal{S})$. Therefore \mathcal{S} does not accept $c(\mathcal{S})$. $\textcolor{red}{\checkmark}$

Case 2 \mathcal{S} rejects $c(\mathcal{S})$. Since \mathcal{S} accepts exactly the encodings of those TMs that reject their own encoding, this implies that \mathcal{S} accepts the input $c(\mathcal{S})$. $\textcolor{red}{\checkmark}$

This implies:

- 1 There is no such TM \mathcal{S} .
- 2 There is no TM $\mathcal{H}2$.

Theorem (Turing 1936)

The halting problem is undecidable.

Decision problems

Theorem (Decision problems for Turing Machines)

The word problem, the emptiness problem, and the equivalence problem are undecidable.

Proof.

If any of these problems were decidable, one could easily derive a decision procedure for the halting problem. □

Closure properties

Theorem (closure under \neg)

*The class of languages accepted by Turing Machines is **not closed** under complement.*

Proof.

If it were closed under complement, $\mathcal{H}2$ would exist.

Theorem (closure under $\cup, \cdot, ^*, \cap$)

*The class of languages accepted by TMs is **closed** under $\cup, \cdot, ^*, \cap$.*

Proof.

Analogous to Type-1-grammars / LBAs.

Diagonalisation

Challenge of the proof:

show for all possible (infinitely many) TMs that none of them can decide the halting problem.

TM	input	$c(\mathcal{A})$	$c(\mathcal{B})$	$c(\mathcal{C})$	$c(\mathcal{D})$	$c(\mathcal{E})$...
\mathcal{A}		X					
\mathcal{B}			X				
\mathcal{C}				X			
\mathcal{D}					X		
\mathcal{E}						X	
...							...

Further diagonalisation arguments

Theorem (Cantor diagonalisation, 1891)

The set of real numbers is uncountable.

Theorem (Epimenides paradox, 6th century BC)

Epimenides [the Cretan] says: “[All] Cretans are always liars.”

Theorem (Russell's paradox, 1903)

$R := \{T \mid T \notin T\}$ Does $R \in R$ hold?

Theorem (Gödel's incompleteness theorem, 1931)

Construction of a sentence in 2nd order predicate logic which states that itself cannot be proved.

Is this important?

- ▶ What is so bad about not being able to decide if a TM halts?
- ▶ Isn't this a purely academic problem?

Ludwig Wittgenstein:

It is very queer that this should have puzzled anyone. [...] If a man says "I am lying" we say that it follows that he is not lying, from which it follows that he is lying and so on. Well, so what? You can go on like that until you are black in the face. Why not? It doesn't matter.

(Lectures on the Foundations of Mathematics, Cambridge 1939)

Does it matter in practice?

It does not only affect halting

Halting is a fundamental property.

If halting cannot be decided, what can be?

Theorem (Rice, 1953)

Every non-trivial semantic property of TMs is undecidable.

non-trivial satisfied by some TMs, not satisfied by others

semantic referring to the accepted language

Undecidability of semantic properties

Example (Property E : TM accepts the set of prime numbers P)

If E is decidable, then so is the halting problem for \mathcal{A} and an input $w_{\mathcal{A}}$.

Approach: Turing Machine \mathcal{E} , input $w_{\mathcal{E}}$

- 1 simulate computation of \mathcal{A} on $w_{\mathcal{A}}$
- 2 decide if $w_{\mathcal{E}} \in P$

Check if \mathcal{E} accepts the set of prime numbers:

yes $\rightsquigarrow \mathcal{A}$ halts with input $w_{\mathcal{A}}$ no $\rightsquigarrow \mathcal{A}$ does not halt on input $w_{\mathcal{A}}$

It does not only affect Turing Machines

Church-Turing-thesis

Every effectively calculable function is a computable function.

computable means calculable by a (Turing) machine
effectively calculable refers to the intuitive idea without reference to a particular computing model

What holds for Turing Machines also holds for

- ▶ unrestricted grammars,
- ▶ *while* programs,
- ▶ von Neumann architecture,
- ▶ Java/C++/Lisp/Prolog programs,
- ▶ future machines and languages

**No interesting property is decidable
for any powerful programming language!**

Undecidable problems in practice

- software development** Does the program match the specification?
- debugging** Does the program have a memory leak?
- malware** Does the program harm the system?
- education** Does the student's TM compute the same function as the teacher's TM?
- formal languages** Do two cf. grammars generate the same language?
- mathematics** Hilbert's tenth problem: find integer solutions for a polynomial with several variables
- logic** Satisfiability of formulas in first-order predicate logic

Yes, it does matter!

Some things that are still possible

- | | |
|---|---|
| It is possible | because |
| to translate a program P from a language into an equivalent one in another language | one specific program is created for P . |
| to detect if a program contains a instruction to write to the hard disk | this is a syntactic property. Deciding if this instruction is eventually executed is impossible in general. |
| to check at runtime if a program accesses the hard disk | this corresponds to the simulation by \mathcal{U} . It is undecidable if the code is never executed. |
| to write a program that gives the correct answer in many “interesting” cases | there will always be cases in which an incorrect answer or none at all is given. |

What can be done?

Can the Turing Machine be “fixed”?

- ▶ undecidability proof does not use any specific TM properties
- ▶ only requirement: existence of universal machine \mathcal{U}
- ▶ TM is not too weak, but **too powerful**
- ▶ different machine models have the same problem (or are weaker)

Alternatives:

- ▶ If possible: use weaker formalisms (modal logic, dynamic logic)
- ▶ use heuristics that work well in many cases, solve remaining ones manually
- ▶ interactive programs

Turing Machines: summary

- ▶ Halting problem: does TM \mathcal{A} halt on input w ?
- ▶ Turing: no TM can decide the halting problem.
- ▶ Rice: no TM can decide any non-trivial semantic property of TMs.
- ▶ Church-Turing: this holds for every powerful machine model.
- ▶ No interesting problem of programs in any powerful programming language is decidable.

Consequences:

- (:(Computers cannot take all work away from computer scientists.
- (:) Computers will never make computer scientists redundant.

Property overview

property	regular (Type 3)	context-free (Type 2)	context-sens. (Type 1)	unrestricted (Type 0)
closure

Goals for Lecture 1

- ▶ Getting acquainted
- ▶ Clarifying practical issues
- ▶ Course outline and motivation
 - ▶ Formal languages
 - ▶ Language classes
 - ▶ Grammars
 - ▶ Automata
 - ▶ Questions
 - ▶ Applications

Practical Issues

- ▶ Lecture times (usually)
 - ▶ Tuesday 12:30-14:00
 - ▶ Wednesday 12:30-14:30
 - ▶ Wednesday 14:00-15:45
 - ▶ No lectures on:
 - ▶ KW37 (September 11.-17.)
 - ▶ September 26th, October 4th, October 25th, October 27th
 - ▶ KW44-KW45 (30.10.-12.11.)
 - ▶ November 17th
- ▶ Written exam
 - ▶ Calender week 47 (20.11.–24.11.)

Lecture 1

Summary Lecture 1

- ▶ Clarifying practical issues
 - ▶ You need running `flex`, `bison`, C compiler, editor!
- ▶ Course outline and motivation
 - ▶ Formal languages
 - ▶ Language classes
 - ▶ Grammars
 - ▶ Automata
 - ▶ Questions
 - ▶ Applications

Feedback round

- ▶ What was the best part of todays lecture?
- ▶ What part of todays lecture has the most potential for improvement?
 - ▶ Optional: how would you improve it?

Outline

Introduction

Regular Languages and Finite Automata

Lecture 17

Lecture 18

Bonus Exercises

Selected Solutions

Goals for Lecture 2

- ▶ Review of last lecture
- ▶ Formal basics of formal languages
- ▶ Operations on words
- ▶ Operations on languages
- ▶ Introduction to regular expressions
 - ▶ Examples
 - ▶ Formal definition

Review

- ▶ Introduction
 - ▶ Language classes
 - ▶ Grammars
 - ▶ Automata
 - ▶ Applications

Lecture 2

Summary

- ▶ Formal languages
 - ▶ Alphabets
 - ▶ Words
 - ▶ Languages
 - ▶ Examples of languages
- ▶ Operations on words and languages
 - ▶ Concatenation
 - ▶ Power
 - ▶ Kleene star
- ▶ Introduction to regular expressions

Remark: Formal languages are *sets*, and hence we can also apply set operations like \cup (union), \cap (intersection), \neg (complement) to them!

Feedback round

	Bonus Exercises
	Selected Solutions

Goals for Lecture 3

- ▶ Review of last lecture
- ▶ Understanding regular expressions
- ▶ Regular expression algebra
 - ▶ Equivalences on regular expressions
 - ▶ Simplifying REs

Review (1)

- ▶ Formal languages
 - ▶ Finite alphabet Σ of symbols/letters
 - ▶ Words are finite sequences of letters from Σ
 - ▶ Languages are (finite or infinite) sets of words
- ▶ Words - properties and operations
 - ▶ $|w|, |w|_a, w[k]$
 - ▶ $w_1 \cdot w_2, w^n$

Review (2)

- ▶ Interesting languages
 - ▶ Binary representations of natural numbers
 - ▶ Binary representations of prime numbers
 - ▶ C functions (over strings)
 - ▶ C functions with input/output pairs
- ▶ Operations on Languages
 - ▶ Product $L_1 \cdot L_2$: Concatenation of one word from each language
 - ▶ Power L^n : Concatenation of n words from L
 - ▶ Kleene Star: L^* : Concat any number of words from L

Remark: Formal languages are *sets*, and hence we can also apply set operations like \cup (union), \cap (intersection), \neg (complement) to them!

Review (3)

► Regular expressions R_Σ

► Base cases:

- $L(\emptyset) = \{\}$
- $L(\epsilon) = \{\epsilon\}$
- $L(a) = \{a\}$ for each $a \in \Sigma$

► Complex cases:

- $L(r_1 + r_2) = L(r_1) \cup L(r_2)$
- $L(r_1 \cdot r_2) = L(r_1 r_2) = L(r_1) \cdot L(r_2)$
- $L(r^*) = L(r)^*$
- $L((r)) = L(r)$ (brackets are used to group expressions)

Lecture 3

Summary

- ▶ Regular expression algebra
 - ▶ REs are equivalent if they describe the same language
 - ▶ REs can be simplified applying equivalences
 - ▶ Recursive definitions: Lemmas of Arden/Salomaa

Feedback round

- ▶ What was the best part of todays lecture?
- ▶ What part of todays lecture has the most potential for improvement?
 - ▶ Optional: how would you improve it?

Bonus Exercises

Selected Solutions

Goals for Lecture 4

- ▶ Review of last lecture
- ▶ Warmup exercise
- ▶ Finite Automata
 - ▶ Graphical representation
 - ▶ Formal definition
 - ▶ Language recognized by an automata
 - ▶ Tabular representation
 - ▶ Exercises

Review (1)

- ▶ Regular expressions R_Σ

- ▶ Base cases:

- ▶ $L(\emptyset) = \{\}$
 - ▶ $L(\epsilon) = \{\epsilon\}$
 - ▶ $L(a) = \{a\}$ for each $a \in \Sigma$

- ▶ Complex cases:

- ▶ $L(r_1 + r_2) = L(r_1) \cup L(r_2)$
 - ▶ $L(r_1 \cdot r_2) = L(r_1 r_2) = L(r_1) \cdot L(r_2)$
 - ▶ $L(r^*) = L(r)^*$
 - ▶ $L((r)) = L(r)$ (brackets are used to group expressions)

Review (2)

- ▶ Regular expression algebra
 - ▶ REs are equivalent if they describe the same language
 - ▶ REs can be simplified applying equivalences
 - ▶ 17 equivalences
 - ▶ Commutativity of $+$, associativity of $+$, \cdot , distributivity (!)
 - ▶ Arden/Salomaa
 - ▶ ...

Warmup Exercise

- ▶ Assume $\Sigma = \{a, b\}$
 - ▶ Find a regular expression for the language L_1 of all words over Σ with at least 3 characters and where the third character is a a .
 - ▶ Describe L_1 formally (i.e. as a set)
 - ▶ Find a regular expression for the language L_2 of all words over Σ with at least 3 characters and where the third character is the same as the third-last character
 - ▶ Describe L_2 formally.

Lecture 4

Summary

- ▶ REs revisited (with exercise)
- ▶ Finite Automata
 - ▶ Graphical representation
 - ▶ Formal definition
 - ▶ Language recognized by an automata
 - ▶ Tabular representation
 - ▶ Exercises

Feedback round

- ▶ What was the best part of todays lecture?
- ▶ What part of todays lecture has the most potential for improvement?
 - ▶ Optional: how would you improve it?

Goals for Lecture 5

- ▶ Review of last lecture
- ▶ Introduction to Nondeterministic Finite Automata
 - ▶ Definitions
 - ▶ Exercises
- ▶ Equivalency of deterministic and nondeterministic finite automata
 - ▶ Converting NFAs to DFAs
 - ▶ Exercises

Review

- ▶ Finite Automata
 - ▶ Graphical representation
 - ▶ Formal definition
 - ▶ Q : Set of states
 - ▶ Σ : Alphabet
 - ▶ δ : Transition function
 - ▶ q_0 : Initial state
 - ▶ F : Final (accepting) states
 - ▶ Language recognized by an automata
 - ▶ $w \in L(A)$ if $\delta'(w) \in F$ or there exist an accepting run of A for w
 - ▶ Tabular representation
 - ▶ Exercises
 - ▶ Open: Automaton for $L_1 = \{ubw \mid u \in \Sigma^*, w \in \Sigma\}$

Lecture 5

Summary

- ▶ Nondeterministic Finite Automata
 - ▶ Q : Set of states
 - ▶ Σ : Alphabet
 - ▶ Δ : Transition *relation* (with ε -transitions!)
 - ▶ q_0 : Initial state
 - ▶ F : Final (accepting) states
- ▶ NFAs and DFAs accept the same class of languages!
- ▶ Converting NFA to DFA
 - ▶ States of $\text{det}(\mathcal{A})$ are elements of 2^Q
 - ▶ ...

 - ▶ States of $\text{det}(A)$ are elements of 2^Q
 - ▶ ...

Lecture 6

Summary

- ▶ Equivalency of regular expressions and NFAs
 - ▶ Construction of an NFA from a regular expression
 - ▶ Base cases each result in a trivial 2-state automaton
 - ▶ Compose automata for composite regular expressions
 - ▶ *Glue* automata together with ϵ -Transitions
 - ▶ Extraction of an RE for a DFA
 - ▶ Determine system of equations
 - ▶ For each state add one alternative for each transition
 - ▶ For accepting states add ϵ .
 - ▶ Solve the system of equations, handling loops with Arden's lemma

Feedback round

Bonus Exercises

Selected Solutions

Goals for Lecture 7

- ▶ Review of last lecture
- ▶ Minimizing DFAs
 - ▶ ... and a first application
- ▶ Exercises

Review

- ▶ Central result: REs, NFAs and DFAs describe the same class of languages (namely **regular languages**)
 - ▶ Proof via constructive algorithms
 - ▶ NFA to DFA already done
 - ▶ RE to NFA and DFA to RE new
- ▶ Construction of an NFA from a regular expression
 - ▶ Base cases each result in a trivial 2-state automaton
 - ▶ Compose automata for composite regular expressions
 - ▶ Glue automata together with ε -Transitions
- ▶ Extraction of an RE for a DFA
 - ▶ Determine system of equations describing language accepted at each state
 - ▶ For each state add one alternative for each transition
 - ▶ For accepting states add ε .
 - ▶ Solve the system of equations, handling loops with Arden's lemma

Homework assignment

- ▶ Get access to an operational Linux/UNIX environment
 - ▶ You can install VirtualBox (<https://www.virtualbox.org>) and then install e.g. Ubuntu (<http://www.ubuntu.com/>) on a virtual machine
 - ▶ For Windows, you can install the **complete** UNIX emulation package Cygwin from <http://cygwin.com>
 - ▶ For MacOS, you can install fink (<http://fink.sourceforge.net/>) or MacPorts (<https://www.macports.org/>) and the necessary tools
- ▶ You will need at least flex, bison, gcc, grep, sed, AWK, make, and a good text editor of your choice

Summary

- ▶ Minimizing DFAs
 - ▶ Identify and merge equivalent states
 - ▶ Result is unique (up to names of states)
 - ▶ Equivalency of REs can be decided by comparison of corresponding minimal DFAs
- ▶ Homework: Get ready for flexing...

Feedback round

- ▶ What was the best part of todays lecture?
- ▶ What part of todays lecture has the most potential for improvement?
 - ▶ Optional: how would you improve it?

Goals for Lecture 8

- ▶ Review of last lecture
- ▶ Beyond regular languages: The Pumping Lemma
 - ▶ Motivation/Lemma
 - ▶ Application of the lemma
 - ▶ Implications
- ▶ Properties of regular languages
 - ▶ Which operations leave regular languages regular?

Review

- ▶ Minimizing DFAs
 - ▶ Identify and merge equivalent states
 - ▶ Result is unique (up to names of states)
 - ▶ Equivalency of REs can be decided by comparison of corresponding minimal DFAs

Lecture 8

Reminder: Homework assignment

- ▶ Install an operational UNIX/Linux environment on your computer
 - ▶ You can install VirtualBox (<https://www.virtualbox.org>) and then install e.g. Ubuntu (<http://www.ubuntu.com/>) on a virtual machine
 - ▶ For Windows, you can install the **complete** UNIX emulation package Cygwin from <http://cygwin.com>
 - ▶ For MacOS, you can install fink (<http://fink.sourceforge.net/>) or MacPorts (<https://www.macports.org/>) and the necessary tools
- ▶ You will need at least flex, bison, gcc, grep, sed, AWK, make, and a good text editor of your choice

Summary

- ▶ Beyond regular languages: The Pumping Lemma
 - ▶ Motivation/Lemma
 - ▶ Application of the lemma ($a^n b^n, a^n b^m, n < m$)
 - ▶ Implications (Nested structures are not regular)
- ▶ Properties of regular languages
 - ▶ Closure properties (union, intersection, ...)
 - ▶ Proof per construction of suitable NFA (union, concatenation, Kleene Star)
 - ▶ Proof per construction of product automaton (intersection)

Selected Solutions

Goals for Lecture 9

- ▶ Completing the theory of regular languages
 - ▶ Complement
 - ▶ Finite languages
 - ▶ Decision problems: Emptiness, word problem, ...
 - ▶ Decision problems: Equivalence, finiteness, ...
 - ▶ Wrap-up

Review

- ▶ The Pumping Lemma
 - ▶ Motivation/Lemma
 - ▶ For every regular language L there exists a k such that any word s with $|s| \geq k$ can be split into $s = uvw$ with $|uv| \leq k$ and $v \neq \varepsilon$ and $uv^h w \in L$ for all $h \in \mathbb{N}$
 - ▶ Use in proofs by contradiction: Assume a language is regular, then derive contradiction
 - ▶ Application of the lemma ($a^n b^n, a^n b^m, n < m$)
 - ▶ Implications (Nested structures are not regular)
 - ▶ Properties of regular languages
 - ▶ The union of two regular languages is regular
 - ▶ The intersection of two regular languages is regular (Solution: Product automaton!)
 - ▶ The concatenation of two regular languages is regular
 - ▶ The Kleene star of a regular language is regular
 - ▶ (The complement of a regular language is regular)

Summary

- ▶ Completing the theory of regular languages
 - ▶ Complement
 - ▶ All finite languages are regular
 - ▶ Decidable for regular languages: Emptiness, word problem
 - ▶ Decidable for regular languages: Equivalence, finiteness
 - ▶ Wrap-up

 - ▶ Systematically consider all decompositions of w
 - ▶ Tabulate all NTS for given subwords bottom-up
 - ▶ Complexity: $O(n^3)$ with $n = |w|$

Lecture 14

Summary

- ▶ Pushdown automata
 - ▶ Transitions must read/can write unlimited stack
 - ▶ Transition can read characters from word (left-to-right only)
 - ▶ Acceptance: Empty stack, empty word
- ▶ Equivalence of context-free grammars and PDAs
 - ▶ From grammar to PDA
 - ▶ Simulate grammar rules on the stack
 - ▶ Highly non-deterministic
 - ▶ From PDA to grammar
 - ▶ Non-terminals represent state changes with removal of a symbols from stack
 - ▶ Complex encoding of transition relation into grammar rules

Selected Solutions

Goals for Lecture 15

- ▶ Review of last lecture
- ▶ Limits of context-free languages
 - ▶ Pumping Lemma II
- ▶ Closure properties of context-free languages
- ▶ Decision problems for context-free languages

Review

- ▶ Pushdown automata
 - ▶ Transitions must read/can write unlimited stack
 - ▶ Transition can read characters from word (left-to-right only)
 - ▶ Acceptance: Empty stack, empty word
- ▶ Equivalence of context-free grammars and PDAs
 - ▶ From grammar to PDA
 - ▶ Simulate grammar rules on the stack
 - ▶ Highly non-deterministic
 - ▶ From PDA to grammar
 - ▶ Non-terminals represent state changes with removal of a symbols from stack
 - ▶ Complex encoding of transition relation into grammar rules

Lecture 15

Summary

- ▶ Limits of context-free languages
 - ▶ Pumping Lemma II
- ▶ Closure properties of context-free languages
 - ▶ The class of context-free languages is closed under $\cup, \cdot, ^*$
 - ▶ The class of context-free languages is not closed under \cap , complement
- ▶ Decision problems for context-free languages
 - ▶ Decidable: Word problem, emptiness problem
 - ▶ Undecidable: Equivalence

Feedback round

- ▶ What was the best part of todays lecture?
- ▶ What part of todays lecture has the most potential for improvement?
 - ▶ Optional: how would you improve it?

Goals for Lecture 16

- ▶ Review of last lecture
- ▶ Introduction to parsing
- ▶ YACC/Bison
 - ▶ Automatic parser generation
 - ▶ Example: desk calculator
- ▶ LALR(1) shift/reduce parsing
- ▶ Parse trees and abstract syntax trees

Review

- ▶ Limits of context-free languages
 - ▶ Pumping Lemma II
 - ▶ Sufficiently long words require sufficiently correspondingly long derivations
 - ▶ Sufficiently long derivations will contain at least one duplicate NTS A
 - ▶ The partial derivation from A to uAv can be repeated
- ▶ Closure properties of context-free languages
 - ▶ The class of context-free languages is closed under $\cup, \cdot, ^*$
 - ▶ The class of context-free languages is not closed under \cap , complement
- ▶ Decision problems for context-free languages
 - ▶ Decidable: Word problem, emptiness problem
 - ▶ Undecidable: Equivalence

Lecture 16

Summary

- ▶ Introduction to parsing
 - ▶ Recognize words (programs) in $L(G)$
 - ▶ Understand structure of words
- ▶ YACC/Bison
 - ▶ Automatic parser generation
 - ▶ Core: Syntax rules with actions (C code)
 - ▶ Whenever input can be *reduced*, action is executed
 - ▶ Often: Manipulation of *semantic values*
 - ▶ Example: desk calculator
- ▶ LALR(1) shift/reduce parsing
 - ▶ Shift input to stack
 - ▶ Reduce RHS to LHS
 - ▶ Use lookahead to reduce ambiguity
- ▶ Parse trees and abstract syntax trees
 - ▶ Parse trees: Represents not just word but derivation
 - ▶ AST: “parse tree without syntactic details”

Bonus Exercises

Assume $\Sigma = \{a, b\}$. Consider the automaton A .

- ▶ Give a formal description of A .
- ▶ Which language $L(A)$ is accepted by A ? Give a formal description.
- ▶ Where does $L(A)$ reside in the Chomsky-hierarchy?
- ▶ Manually find a regular expression R with $L(R) = L(A)$.
- ▶ Generate a system of equations for A and generate a regular expression R_S for $L(A)$ by solving this. Compare your result to the previous one.
- ▶ Convert A into a regular grammar G with $L(A) = L(G)$.

- ▶ Can $L(A)$ be pumped? If yes, provide an example of a pumpable word.
- ▶ Generalize A to recognize $L_3 = \{w \in \Sigma^* \mid |w|_a \text{ modulo } 3 = 0\}$
- ▶ Form the product automaton P to find $L(A) \cap L_3$.
- ▶ Minimize P .
- ▶ Systematically construct a NFA D_A for R_S .
- ▶ Convert D_R to a DFA.

Bonus Exercises

Selected Solutions

Equivalence of regular expressions

Solution to Exercise: Algebra on regular expressions (1)

► Claim: $r^* \doteq \varepsilon + r^*$

$$\varepsilon + r^* \doteq \varepsilon + \varepsilon + r^*r \quad (13)$$

Proof:

$$\begin{aligned} &\doteq \varepsilon + r^*r \quad (9) \\ &\doteq r^* \quad (13) \end{aligned}$$

Simplification of regular expressions

Solution to Exercise: Algebra on regular expressions (2)

$$\begin{aligned} r &= 0(\varepsilon + 0 + 1)^* + (\varepsilon + 1)(1 + 0)^* + \varepsilon \\ &\stackrel{14,1}{\dot{=}} 0(0 + 1)^* + (\varepsilon + 1)(0 + 1)^* + \varepsilon \\ &\stackrel{7}{\dot{=}} 0(0 + 1)^* + \varepsilon(0 + 1)^* + 1(0 + 1)^* + \varepsilon \\ &\stackrel{5}{\dot{=}} 0(0 + 1)^* + (0 + 1)^* + 1(0 + 1)^* + \varepsilon \\ &\stackrel{1,7}{\dot{=}} \varepsilon + (0 + 1)(0 + 1)^* + (0 + 1)^* \\ &\stackrel{16}{\dot{=}} \varepsilon + (0 + 1)^*(0 + 1) + (0 + 1)^* \\ &\stackrel{13}{\dot{=}} (0 + 1)^* + (0 + 1)^* \\ &\stackrel{9}{\dot{=}} (0 + 1)^*. \end{aligned}$$

Application of Arto's lemma

Solution to Exercise: Algebra on regular expressions (3)

- ▶ Show that $u = 10(10)^* \doteq 1(01)^*0$
- ▶ Idea: u is of the form ts^* with:
 - ▶ $t = 10$
 - ▶ $s = 10$
 - ▶ This suggest Arto's Lemma. To apply the lemma, we must show that $r = 1(01)^*0 \doteq rs + t$
- ▶
$$\begin{aligned} rs + t &= 1(01)^*010 + 10 \\ &\doteq 1((01)^*010 + 0) \quad (\text{factor out } 1) \end{aligned}$$
- ▶ So:
$$\begin{aligned} &\doteq 1((01)^*01 + \varepsilon)0 \quad (\text{factor out } 0) \\ &\doteq 1(01)^*0 \quad (14) \\ &= r \end{aligned}$$
- ▶ Since $L(s) = \{10\}$ (and hence $\varepsilon \notin L(s)$), we can apply Arto and rewrite $r \doteq ts^* \doteq 10(10)^*$.

Back

Transformation into DFA (1)

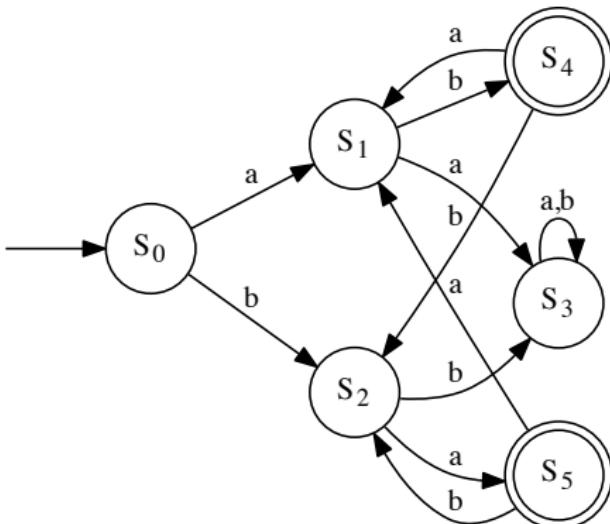

- ▶ Incremental computation of \hat{Q} and $\hat{\delta}$:
 - ▶ Initial state $S_0 = ec(q_0) = \{q_0, q_1, q_2\}$
 - ▶ $\hat{\delta}(S_0, a) = \delta^*(q_0, a) \cup \delta^*(q_1, a) \cup \delta^*(q_2, a) = \{\} \cup \{\} \cup \{q_4\} = \{q_4\} = S_1$
 - ▶ $\hat{\delta}(S_0, b) = \{q_3\} = S_2$
 - ▶ $\hat{\delta}(S_1, a) = \{\} = S_3$
 - ▶ $\hat{\delta}(S_1, b) = ec(q_6) = \{q_6, q_7, q_0, q_1, q_2\} = S_4$
 - ▶ $\hat{\delta}(S_2, a) = \{q_5, q_7, q_0, q_1, q_2\} = S_5$
 - ▶ $\hat{\delta}(S_2, b) = \{\} = S_3$
 - ▶ $\hat{\delta}(S_3, a) = \{\} = S_3$
 - ▶ $\hat{\delta}(S_3, b) = \{\} = S_3$
 - ▶ $\hat{\delta}(S_4, a) = \{q_4\} = S_1$
 - ▶ $\hat{\delta}(S_4, b) = \{q_3\} = S_2$
 - ▶ $\hat{\delta}(S_5, a) = \{q_4\} = S_1$
 - ▶ $\hat{\delta}(S_5, b) = \{q_3\} = S_2$
- ▶ $\hat{F} = \{S_4, S_5\}$ (since $q_7 \in S_4, q_7 \in S_5$)

Transformation into DFA (2)

- ▶ $\det(\mathcal{A}) = (\hat{Q}, \Sigma, \hat{\delta}, S_0, \hat{F})$
 - ▶ $\hat{Q} = \{S_0, S_1, S_2, S_3, S_4, S_5\}$
 - ▶ $\hat{F} = (S_4, S_5)$
 - ▶ $\hat{\delta}$ given by the table below

	$\hat{\delta}$	a	b
$\rightarrow S_0$		S_1	S_2
S_1		S_3	S_4
S_2		S_5	S_3
S_3		S_3	S_3
$*S_4$		S_1	S_2
$*S_5$		S_1	S_2

- ▶ Regexp:
 $L(\mathcal{A}) = L((ab + ba)(ab + ba)^*)$

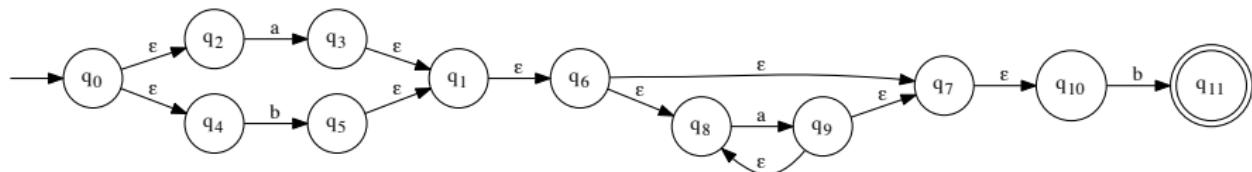

Back to exercise

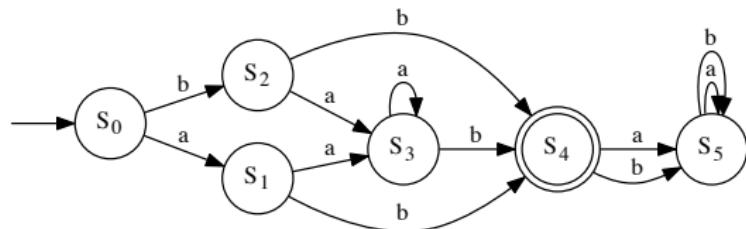

Transformation of RE into NFA

Systematically construct an NFA accepting the same language as the regular expression $(a + b)a^*b$.

Solution:

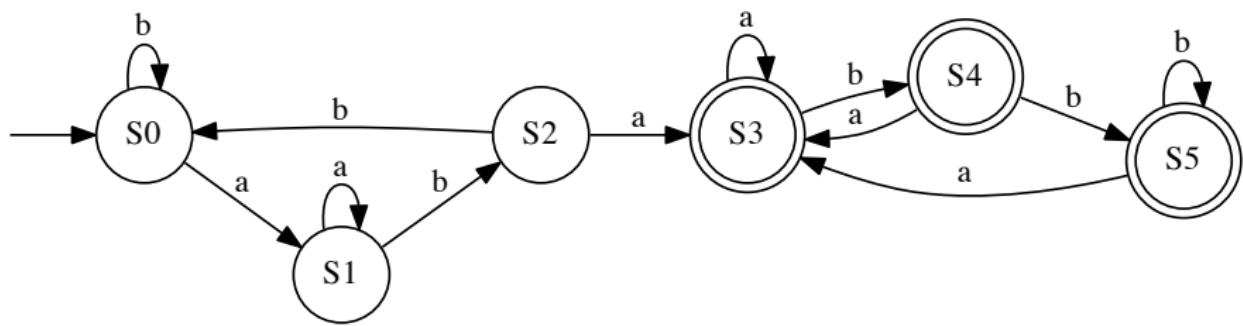

Corresponding DFA:

[Back to exercise](#)

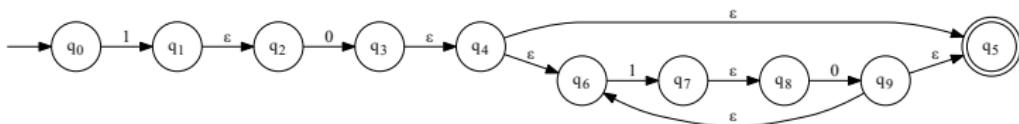

Solution: NFA to DFA “aba”

Show $10(10)^* \doteq 1(01)^*0$ via minimal DFAs (1)

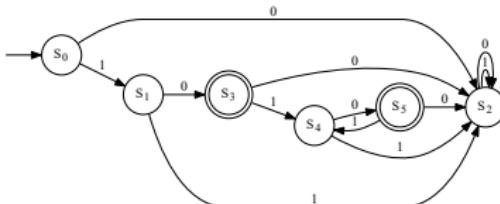

- ▶ Step 1: NFA for $10(10)^*$:

	epsilon	0	1
->	q0 { } { } {q1}		
	q1 {q2} { } { }		
	q2 { } {q3} { }		
	q3 {q4} { } { }		
	q4 {q5, q6} { } { }		
*	q5 { } { } { }		
	q6 { } { } {q7}		
	q7 {q8} { } { }		
	q8 { } {q9} { }		
	q9 {q5, q6} { } { }		

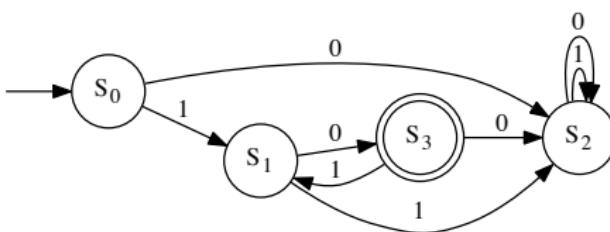

Show $10(10)^* \doteq 1(01)^*0$ via minimal DFAs (2)

- ▶ Step 2: DFA \mathcal{A} for $10(10)^*$:

- ▶ Step 3: Minimizing of \mathcal{A}

	S_0	S_1	S_2	S_3	S_4	S_5
S_0	o	x	x	x	x	x
S_1	x	o	x	x	o	x
S_2	x	x	o	x	x	x
S_3	x	x	x	o	x	o
S_4	x	o	x	x	o	x
S_5	x	x	x	o	x	o

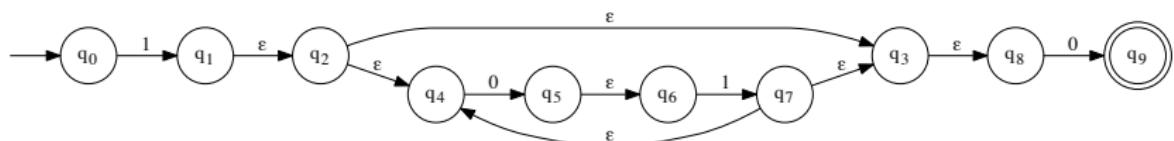

Result: (S_1, S_4) and (S_3, S_5) can be merged

Show $10(10)^* \doteq 1(01)^*0$ via minimal DFAs (3)

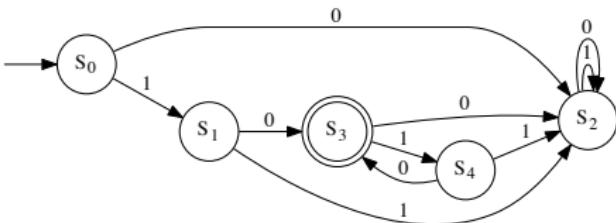

- ▶ Step 4: NFA zu $1(01)^*0$:

	epsilon	0	1
-> q0	{}	{}	{q1}
q1	{q2}	{}	{}
q2	{q3, q4}	{}	{}
q3	{q8}	{}	{}
q4	{}	{q5}	{}
q5	{q6}	{}	{}
q6	{}	{}	{q7}
q7	{q4, q3}	{}	{}
q8	{}	{}	{q9}
* q9	{}	{}	{}

Show $10(10)^* \doteq 1(01)^*0$ via minimal DFAs (4)

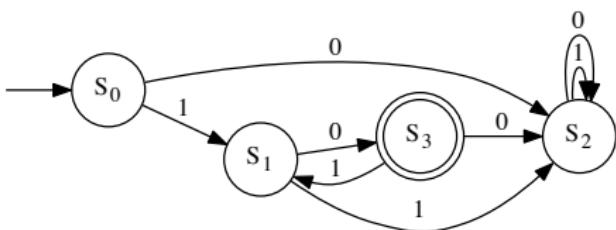

- ▶ Step 5: DFA \mathcal{B} for $1(01)^*0$

- ▶ Step 6: Minimization of \mathcal{B}

	S_0	S_1	S_2	S_3	S_4
S_0	o	x	x	x	x
S_1	x	o	x	x	o
S_2	x	x	o	x	x
S_3	x	x	x	o	x
S_4	x	o	x	x	o

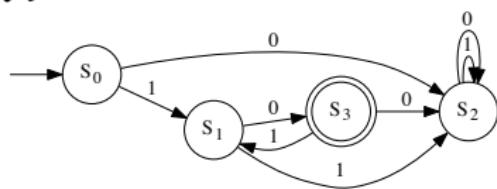

Result: (S_1, S_4) can be merged

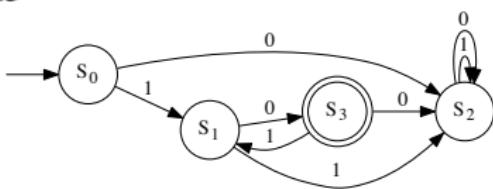

Show $10(10)^* \doteq 1(01)^*0$ via minimal DFAs (5)

- ▶ Step 7: Comparision of \mathcal{A}^- and \mathcal{B}^-

\mathcal{A}^-

\mathcal{B}^-

- ▶ Result: The two automata are identical, hence the two original regular expressions describe the same languages.

[Back to exercise](#)

[Back to review](#)

Pumping lemma

Solution to $a^n b^m$ with $n < m$

- ▶ Proposition: $L = \{a^n b^m \mid n < m\}$ is not regular.
- ▶ Proof by contradiction. We assume L is regular
- ▶ Then: $\exists k \in \mathbb{N}$ with:
 - ▶ $\forall s \in L$ with $|s| \geq k : \exists u, v, w \in \Sigma^*$ such that
 - ▶ $s = uvw$
 - ▶ $|uv| \leq k$
 - ▶ $v \neq \varepsilon$
 - ▶ $uv^h w \in L$ for all $h \in \mathbb{N}$
- ▶ We consider the word $s = a^k b^{k+1} \in L$
 - ▶ Since $|uv| \leq k$: $u = a^i, v = a^j, w = a^l b^{k+1}$ and $j > 0, i + j + l = k$
 - ▶ Now consider $s' = uv^2w$. According to the pumping lemma, $s' \in L$.
But $s' = a^i a^j a^j a^l b^{k+1} = a^{i+j+l+j} b^{k+1} = a^{k+j} b^{k+1}$. Since $j \in \mathbb{N}, j > 0$: $k + j \not< k + 1$. Hence $s' \notin L$. This is a contradiction. Hence the assumption is wrong, and the original proposition is true. q.e.d.

[Back to exercise](#)

Solution: Pumping lemma (Prime numbers)

- ▶ Proposition: $L = \{a^p \mid p \in \mathbb{P}\}$ is not regular (where \mathbb{P} is the set of all prime numbers)
- ▶ Proof: By contradiction, using the pumping lemma.
 - ▶ Assumption: L is regular. Then there exist a k such that all words in L with at least length k can be pumped.
- ▶ Consider the word $s = a^p$, where $p \in \mathbb{P}, p \geq k$
 - ▶ Then there are $u, v, w \in \Sigma^*$ with $uvw = s$, $|uv| \leq k$, $v \neq \varepsilon$, and $uv^h w \in L$ for all $h \in \mathbb{N}$.
 - ▶ We can write $u = a^i, v = a^j, w = a^l$ with $i + j + l = p$
 - ▶ So $s = a^i a^j a^l$ and $a^i a^{j \cdot h} a^l \in L$ for all $h \in \mathbb{N}$.
 - ▶ Consider $h = p + 1$. Then $a^i a^{j \cdot (p+1)} a^l \in L$
 - ▶ $a^i a^{j \cdot (p+1)} a^l = a^i a^{jp+j} a^l = a^i a^{jp} a^j a^l = a^i a^j a^l a^{jp} = a^p a^{jp} = a^{(j+1)p}$
 - ▶ But $(j+1)p \notin \mathbb{P}$, since $j+1 > 1$ and $p > 1$, and $(j+1)p$ thus has (at least)two non-trivial divisors.
 - ▶ Thus $a^{(j+1)p} \notin L$. This violates the pumping lemma and hence contradicts the assumption. Thus the assumption is wrong and the proposition holds.

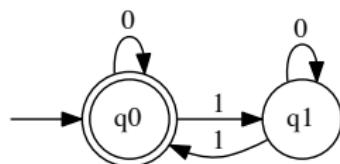

q.e.d.

[Back to exercise](#)

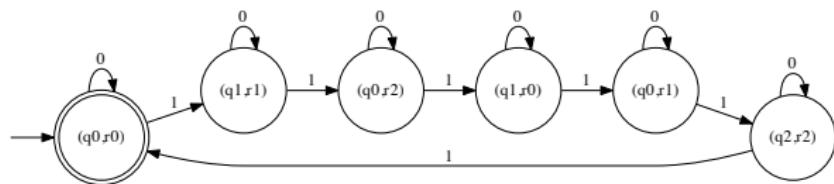

Solution: Product automaton for $L_1 \cap L_2$

Solution to Exercise: Product automaton

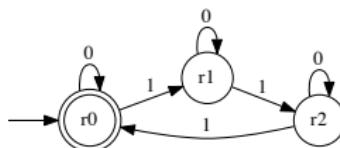

A_1 :

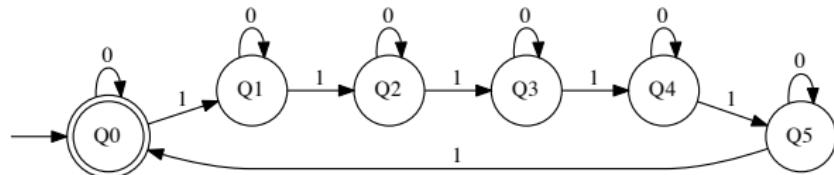

$A_1 \times A_2$ for $L_1 \cap L_2$:

A_2 :

Äquivalent Automaton for $L_1 \cap L_2$:

Solution: Transformation to Chomsky Normal Form (1)

Compute the Chomsky normal form of the following grammar:

$$G = (N, \Sigma, P, S)$$

- ▶ $N = \{S, A, B, C, D, E\}$
- ▶ $\Sigma = \{a, b\}$

$$\begin{array}{ll} S \rightarrow AB|SB|BDE & C \rightarrow SB \\ \text{▶ } P : \quad A \rightarrow Aa & D \rightarrow E \\ & B \rightarrow bB|BaB|ab \\ & & E \rightarrow \varepsilon \end{array}$$

Step 1: ε -Elimination

- ▶ Nullable NTS: $N = \{E, D\}$
 - $S \rightarrow BD$ (from $S \rightarrow BDE$, $\beta_1 = BD$, $\beta_2 = \varepsilon$)
 - $S \rightarrow BE$ (from $S \rightarrow BDE$, $\beta_1 = B$, $\beta_2 = E$)
- ▶ New rules:
 - $S \rightarrow B$ (from $S \rightarrow BD$ or $S \rightarrow BE$, $\beta_1 = B$, $\beta_2 = \varepsilon$)
 - $D \rightarrow \varepsilon$ (from $D \rightarrow E$, $\beta_1 = \varepsilon$, $\beta_2 = \varepsilon$)
- ▶ Remove $E \rightarrow \varepsilon$, $D \rightarrow \varepsilon$

Solution: Transformation to Chomsky Normal Form (2)

Step 2: Elimination of Chain Rules.

- ▶ Current chain rules: $S \rightarrow B, D \rightarrow E$
- ▶ Eliminate $S \rightarrow B$:
 - ▶ $N(S) = \{B\}$
 - ▶ New rules: $S \rightarrow bB, S \rightarrow BaB, S \rightarrow ab$
- ▶ Eliminate $D \rightarrow E$
 - ▶ $N(D) = \{E\}$
 - ▶ E has no rule, therefore no new rules!
- ▶ Current state of P :

$$S \rightarrow AB|SB|BDE|BD|BE|bB|BaB|ab$$

$$A \rightarrow Aa$$

$$C \rightarrow SB$$

$$B \rightarrow bB|BaB|ab$$

Solution: Transformation to Chomsky Normal Form (3)

Step 3: Reducing the grammar

- ▶ Terminating symbols: $T = \{S, B, C\}$ (A, D, E do not terminate)
 - ▶ Remove all rules that contain A, E, D . Remaining:

$$\begin{array}{lcl} S & \rightarrow & SB|bB|BaB|ab \\ B & \rightarrow & bB|BaB|ab \end{array} \qquad \begin{array}{lcl} C & \rightarrow & SB \end{array}$$

- ▶ Reachable symbols: $R = \{S, B\}$ (C is not reachable)
 - ▶ Remove all rules containing C . Remaining:

$$\begin{array}{lcl} S & \rightarrow & SB|bB|BaB|ab \\ B & \rightarrow & bB|BaB|ab \end{array}$$

Solution: Transformation to Chomsky Normal Form (4)

Step 4: Introduce new non-terminals for terminals

- ▶ New rules: $X_a \rightarrow a, X_b \rightarrow b$. Result:

$$\begin{array}{lll} S & \rightarrow & SB|X_bB|BX_aB|X_aX_b \\ B & \rightarrow & X_bB|BX_aB|X_aX_b \end{array} \quad \begin{array}{lll} X_a & \rightarrow & a \\ X_b & \rightarrow & b \end{array}$$

Step 5: Introduce new non-terminals to break up long right hand sides:

- ▶ Problematic RHS: BX_aB (in two rules)
- ▶ New rule: $C_1 \rightarrow X_aB$. Result:

$$\begin{array}{lll} S & \rightarrow & SB|X_bB|BC_1|X_aX_b \\ B & \rightarrow & X_bB|BC_1|X_aX_b \\ C_1 & \rightarrow & X_aB \end{array} \quad \begin{array}{lll} X_a & \rightarrow & a \\ X_b & \rightarrow & b \end{array}$$

Solution: Transformation to Chomsky Normal Form (5)

Final grammar: $G' = (N', \Sigma, P', S)$ with

► $N' = \{S, B, C_1, X_a, X_b\}$

► $\Sigma = \{a, b\}$

$$S \rightarrow SB|X_bB|BC_1|X_aX_b \quad X_a \rightarrow a$$

$$\begin{aligned} P' : B &\rightarrow X_bB|BC_1|X_aX_b & X_b &\rightarrow b \\ C_1 &\rightarrow X_aB \end{aligned}$$

[Back to exercise](#)

Solution: PDA to Grammar (1)

$$\mathcal{A} = (Q, \Sigma, \Gamma, \Delta, 0, Z)$$

- ▶ $Q = \{0, 1\}$
- ▶ $\Sigma = \{a, b\}$
- ▶ $\Gamma = \{A, Z\}$

$$\Delta : \begin{array}{llllll} (1) & 0 & \varepsilon & Z & \rightarrow & \varepsilon & 0 \\ (2) & 0 & a & Z & \rightarrow & AZ & 0 \\ (3) & 0 & a & A & \rightarrow & AA & 0 \\ (4) & 0 & b & A & \rightarrow & \varepsilon & 1 \\ (5) & 1 & b & A & \rightarrow & \varepsilon & 1 \\ (6) & 1 & \varepsilon & Z & \rightarrow & \varepsilon & 1 \end{array}$$

$$G = (N, \Sigma, P, S)$$

- ▶ $N = \{S, [0A0], [0A1], [1A0], [1A1], [0Z0], [0Z1], [1Z0], [1Z1]\}$
- ▶ Σ and S as given

- ▶ Start rules for P :

- ▶ $S \rightarrow [0Z0]$
- ▶ $S \rightarrow [0Z1]$

- ▶ From transitions:

- ▶ From (1): $[0Z0] \rightarrow \varepsilon$
- ▶ From (4): $[0A1] \rightarrow b$
- ▶ From (5): $[1A1] \rightarrow b$
- ▶ From (6): $[1Z1] \rightarrow \varepsilon$
- ▶ (2) and (3): Next page

Solution: PDA to Grammar (2)

$$\mathcal{A} = (Q, \Sigma, \Gamma, \Delta, 0, Z)$$

- $Q = \{0, 1\}$
- $\Sigma = \{a, b\}$
- $\Gamma = \{A, Z\}$

$$\Delta : \begin{array}{ccccccc} (1) & 0 & \varepsilon & Z & \rightarrow & \varepsilon & 0 \\ (2) & 0 & a & Z & \rightarrow & AZ & 0 \\ (3) & 0 & a & A & \rightarrow & AA & 0 \\ (4) & 0 & b & A & \rightarrow & \varepsilon & 1 \\ (5) & 1 & b & A & \rightarrow & \varepsilon & 1 \\ (6) & 1 & \varepsilon & Z & \rightarrow & \varepsilon & 11 \end{array}$$

Computing of P continued:

► From (2):

- $[0Z0] \rightarrow a[0A0][0Z0]$
- $[0Z0] \rightarrow a[0A1][1Z0]$
- $[0Z1] \rightarrow a[0A0][0Z1]$
- $[0Z1] \rightarrow a[0A1][1Z1]$

► From (3):

- $[0A0] \rightarrow a[0A0][0A0]$
- $[0A0] \rightarrow a[0A1][1A0]$
- $[0A1] \rightarrow a[0A0][0A1]$
- $[0A1] \rightarrow a[0A1][1A1]$

Solution: PDA to Grammar (3)

Full grammar $G = \{N, \Sigma, P, S\}$

- ▶ $N = \{S, [0A0], [0A1], [1A0], [1A1], [0Z0], [0Z1], [1Z0], [1Z1]\}$

- ▶ $\Sigma = \{a, b\}$

- ▶ $P:$

- ▶ $S \rightarrow [0Z0]$
- ▶ $S \rightarrow [0Z1]$
- ▶ $[0Z0] \rightarrow \epsilon$
- ▶ $[0A1] \rightarrow b$
- ▶ $[1A1] \rightarrow b$
- ▶ $[1Z1] \rightarrow \epsilon$
- ▶ $[0Z0] \rightarrow a[0A0][0Z0]$
- ▶ $[0Z0] \rightarrow a[0A1][1Z0]$
- ▶ $[0Z1] \rightarrow a[0A0][0Z1]$
- ▶ $[0Z1] \rightarrow a[0A1][1Z1]$
- ▶ $[0A0] \rightarrow a[0A0][0A0]$
- ▶ $[0A0] \rightarrow a[0A1][1A0]$
- ▶ $[0A1] \rightarrow a[0A0][0A1]$
- ▶ $[0A1] \rightarrow a[0A1][1A1]$

- ▶ Terminating: $T = \{[0Z0], [0A1], [1A1], [1Z1], S, [0Z1]\}$
- ▶ Remaining rules:

- 1 $S \rightarrow [0Z0]$
- 2 $S \rightarrow [0Z1]$
- 3 $[0Z0] \rightarrow \epsilon$
- 4 $[0A1] \rightarrow b$
- 5 $[1A1] \rightarrow b$
- 6 $[1Z1] \rightarrow \epsilon$
- 7 $[0Z1] \rightarrow a[0A1][1Z1]$
- 8 $[0A1] \rightarrow a[0A1][1A1]$

- ▶ Reachable:

$R = \{S, [0Z0], [0Z1], [0A1], [1Z1], [1A1]\}$

- ▶ No change!

Solution: PDA to Grammar (4)

► P :

- 1 $S \rightarrow [0Z0]$
- 2 $S \rightarrow [0Z1]$
- 3 $[0Z0] \rightarrow \varepsilon$
- 4 $[0A1] \rightarrow b$
- 5 $[1A1] \rightarrow b$
- 6 $[1Z1] \rightarrow \varepsilon$
- 7 $[0Z1] \rightarrow a[0A1][1Z1]$
- 8 $[0A1] \rightarrow a[0A1][1A1]$

► Derivation of ε :

$$\triangleright S \Rightarrow_1 [0Z0] \Rightarrow_3 \varepsilon$$

► Derivation of ab :

$$\triangleright S \Rightarrow_2 [0Z1] \Rightarrow_7 a[0A1][1Z1] \Rightarrow_4 ab[1Z1] \Rightarrow_6 ab$$

► Derivation of $aabb$:

$$\triangleright S \Rightarrow_2 [0Z1] \Rightarrow_7 a[0A1][1Z1] \Rightarrow_8 aa[0A1][1A1][1Z1] \Rightarrow_4 aab[1A1][1Z1] \Rightarrow_5 aabb[1Z1] \Rightarrow_6 aabb$$
